CALIFORNIA ENERGY COMMISSION
1516 NINTH STREET
HEARING ROOM A
SACRAMENTO, CALIFORNIA

THURSDAY, FEBRUARY 8, 2001

10:07 A.M.

Reported by:
Valorie Phillips
Contract No. 150-99-001

PETERS SHORTHAND REPORTING CORPORATION (916) 362-2345

COMMISSIONERS PRESENT

Robert A. Laurie, Commissioner, Presiding Member

Robert Pernell, Commissioner, Associate Member

Ellen Townsend-Smith, Advisor

Scott Tomashefsky, Advisor

STAFF PRESENT

Richard Buell

Joe O'Hagan

PUBLIC ADVISER

Roberta Mendonca

ALSO PRESENT

Edward Anton, Interim Executive Director

Craig M. Wilson, Chief Counsel

State Water Resources Control Board

Kamyar Guivetchi

Douglas K. Osugi

Department of Water Resources

Wayne J. Hoffman

Duke Energy North America

Brian F. Waters

Duke Engineering & Services

John S. Maulbetsch

Consultant

Michael B. Jackson, Attorney

Regional Council of Rural Counties

Michael DiFilippo

Water & Wastewater Process Improvement

Consultant

ALSO PRESENT

Gerald H. Meral
Planning and Conservation League

Kaitilin Gaffney
Center for Marine Conservation

Proceedings	1
Opening Remarks	1
Introductions	1,2
CEC Staff Overview	2
Panel 1: Water Supply and Water Regulations	5
Overview	5
Water Rights, Water Quality and Water Policy, E. Anton and C. Wilson (SWRCB)	5,15
Near-and-Long-Term Availability of Water, K. Guivetchi and D. Osugi (DWR)	26
Cooling Alternatives and Once-Through Cooling, W. Hoffman and B. Waters (Duke Energy)	68
Afternoon Session	100
Panel 2: Technological Solutions	100
Cooling Technologies, J. Maulbetsch	101
Use of Degraded Water, M. DiFilippo	122
Panel 3: Water Policy	142
Water Policy, M. Jackson (RCRC)	143
Water Policy, G. Meral (PCL)	150
Water Policy, K. Gaffney (Center for Marine Conservation)	159
Closing Remarks	167
Adjournment	168
Certificate of Reporter	169

1 P R O C E E D I N G S

2 10:12 a.m.

3 PRESIDING MEMBER LAURIE: Ladies and
4 gentlemen, good morning and welcome. My name is
5 Robert Laurie, Commissioner at the Energy
6 Commission. Myself, along with my colleague to my
7 right, Commissioner Pernell, make up the
8 Commission's Siting Committee.

9 And the purpose of today's meeting is a
10 furtherance of our series of workshops on
11 potential barriers to long-term generation
12 prospects in the State of California.

13 Further introductions, to my left is my
14 Advisor, Mr. Scott Tomashefsky; and to
15 Commissioner Pernell's right is Commissioner
16 Pernell's Advisor, Ellie Townsend-Smith.

17 I think perhaps -- first of all, do you
18 all have agendas? Are agendas available? Thank
19 you. My intent is to ask Mr. O'Hagan or other
20 staff to offer introductory comments and introduce
21 our speakers for this morning.

22 Before we do that, Commissioner Pernell,
23 did you have any comments you'd like to make at
24 this time, sir?

25 COMMISSIONER PERNELL: No comments.

1 Just welcome, everyone, to the Commission and we
2 look forward to a very informative workshop today.

3 PRESIDING MEMBER LAURIE: Joe.

4 MR. O'HAGAN: Thank you, Commissioner --

5 PRESIDING MEMBER LAURIE: Just a
6 warning. Our microphones work in such a fashion
7 that you darn near have to get intimate with those
8 things.

9 (Laughter.)

10 PRESIDING MEMBER LAURIE: So gain your
11 familiarity now.

12 MR. O'HAGAN: Thank you, Commissioner.
13 My name is Joe O'Hagan; I'm a staff member at the
14 California Energy Commission.

15 To my left, far left, is Craig Wilson,
16 Chief Legal Counsel for the State Water Resources
17 Control Board. And to my immediate left is Ed
18 Anton, also with the State Water Resources Control
19 Board.

20 And to my right is Kamyar Guivetchi,
21 Department of Water Resources. And there's Wayne
22 Hoffman of Duke Energy and Brian Waters of Duke
23 Energy, as well.

24 These are this morning's speakers.
25 Staff had prepared a short paper talking about

1 water supply issues in California. It was really
2 a gloss on the issues, trying to identify some of
3 the issues associated with different water
4 sources, opportunities for water conservation and
5 wastewater discharge, as well. The focus was on
6 water supply in response to the order instigating
7 the investigation.

8 Staff's perspective is that looking back
9 on our siting case history is that most water
10 supply proposals that we've dealt with are
11 workable. But one of the big constraints that
12 I've seen, certainly, personally, is the lack of
13 information.

14 Certainly the water supply in California
15 is a great concern to many people. And the siting
16 cases, as the Committee's aware, where public
17 concern always addresses the water issue.

18 And one of the problems that staff has
19 dealt with is that of acquiring sufficient
20 information to be able to do a full analysis of
21 the proposed water supply to projects, as well as
22 alternatives. Because certainly there are
23 alternatives available to any water supply
24 proposal in California.

25 And I think that we do have some numbers

1 in the staff water supply paper that are in terms
2 of water use by power plant generation in
3 California that are vague estimates, but I could
4 honestly say I don't think it's a very large
5 percentage. Certainly not in comparison to other
6 agriculture or urban water demand in the state.

7 But, once again, there can be local
8 impacts from the proposed water supply; and once
9 again, it's certainly a concern for the local
10 community for power plant proposals.

11 And with that I'd like to turn it over
12 to Mr. Anton.

13 MR. ANTON: My name's Edward Anton; I'm
14 the Acting Executive Director for the State Water
15 Resources Control Board.

16 PRESIDING MEMBER LAURIE: Thank you,
17 sir. We very much appreciate you being here this
18 morning.

19 MR. ANTON: Certainly. I do want to say
20 that we have another meeting that's going on at a
21 parallel time, and both Craig Wilson and I would
22 like to leave after we get through with our
23 portion of this so we can attend the other
24 meeting. We have two staff --

25 PRESIDING MEMBER LAURIE: Everybody

1 seems to be in multiple meetings these days, so
2 please, feel free.

3 MR. ANTON: We do have two very
4 knowledgeable staff counsels here who can stay
5 longer, and answer questions should they come up
6 at a later time.

7 PRESIDING MEMBER LAURIE: Thank you.

8 MR. ANTON: The State Water Resources
9 Control Board and the Regional Water Quality
10 Control Boards that we work with regulate two
11 aspects of the water.

12 The first is water supply, which seems
13 to be the main thrust of your workshop today;
14 although on your agenda you do mention water
15 quality. We also regulate water quality in the
16 state, principally through the Regional Water
17 Quality Control Boards under overall guidance from
18 the State Water Resources Control Board.

19 From the water supply standpoint much of
20 the impact is from a policy that the Board adopted
21 some time ago that attempts to define where water
22 for power plants should come from. The principal
23 push of that was recognition that the state has a
24 limited water supply.

25 I know you'll hear later from the

1 Department of Water Resources about the problems
2 with the state's water supply.

3 But, simply said, we, in California, use
4 more water than we have. And one would wonder how
5 we can do that. A major factor is we're mining
6 our fresh water from groundwater. And at some
7 point that will have to stop, and we'll have to
8 either permanently reduce the amount of water, or
9 somehow find sources such as desalting, which
10 typically takes a lot of power to do.

11 So the state did adopt a policy that set
12 up a priority list of pushing use of waters that
13 might not otherwise be used for the state's water
14 supply first. And it does set up a priority,
15 water that might have been discharged --
16 wastewater that would be discharged to the ocean,
17 and thereby lost, other saline waters, the ocean,
18 itself, for once-through cooling, and at the last
19 of the priorities would be other fresh water
20 supply sources.

21 That policy was not set up as an
22 absolute, and it's recognized by both your staff
23 and the state board that if all else is given and
24 the analysis is thorough, that the water supply
25 should not be an impediment to the siting and

1 development of a power plant.

2 In any case, though, it does call for a
3 look to determine if some alternative's available
4 to reduce the amount of water.

5 That policy also includes provisions for
6 disposal of wastewater from power plants,
7 principally aimed at blow-down from cooling
8 systems. As you're certainly aware, a water-based
9 cooling system that relies on evaporation,
10 concentrates the salts in that water.

11 If a cooling system of that sort is
12 located inland, there is often a problem with the
13 disposal of the waste because of the water quality
14 considerations of that blow-down water. The
15 policy calls for disposal to salt sinks or lined
16 ponds. Other alternatives, of course, would be to
17 a wastewater system that discharges to the ocean.

18 But, in any case, disposal of the
19 wastewater is a problem that does need to be
20 considered if evaporative cooling is a portion of
21 the process.

22 I'll talk just briefly about the water
23 quality aspects. In California we administer the
24 federal program of the national pollutant
25 discharge elimination system, which is a federal

1 permit program for all discharges of waste to
2 navigable waters.

3 The USEPA has established rules for
4 power plants. And also the federal law requires
5 states to adopt water quality standards for
6 various types of discharges, or various types of
7 pollutants. And the state has adopted a water
8 quality control plan for the discharge of thermal
9 waste. In most instances it would apply. It's
10 for the ocean, or coastal waters, interstate
11 waters and estuarine waters.

12 There are also standards for thermal
13 waste for discharge to inland waters contained in
14 water quality control plans adopted by the
15 Regional Water Quality Control Boards.

16 PRESIDING MEMBER LAURIE: And who adopts
17 those standards? That's your shop that does that?

18 MR. ANTON: The state board adopts the
19 overall standards that apply statewide. And that
20 includes -- there is an existing policy, or water
21 quality control plan for thermal discharge that
22 applies to ocean waters, interstate waters,
23 estuarine waters and other tidal type waters.

24 But that does not apply to some inland
25 waters, and we'd have to rely on the water quality

1 control plans adopted by the Regional Water
2 Quality Control Boards, which are subsequently
3 approved by the state board before they go into
4 effect.

5 An interesting thing about water quality
6 standards for the discharge of heat, the Federal
7 Clean Water Act includes a provision, which is
8 section 316(a) of the Act, that essentially says
9 you can waive all the thermal standards as long as
10 you can show the balanced population of fish,
11 shellfish and wildlife -- balanced indigenous
12 population of fish, shellfish and wildlife can be
13 supported on the water body where the discharge
14 occurs.

15 And that particular provision is
16 incorporated into the state thermal plan as an
17 exception process.

18 The difficult thing about that, when we
19 were talking about siting a facility in the short
20 term, is to make such a showing takes a fair
21 amount of time to develop the studies necessary to
22 support that showing.

23 Many power plants have gone through that
24 process and at present are operating under those
25 types of exception, or are in the process of

1 getting one.

2 For instance, the Moss Landing Power
3 Plant was granted such an exception by the
4 Regional Water Quality Control Board. That
5 exception is now at the state board for its
6 approval.

7 The federal law also sets up a section
8 called section 316(b) that talks about cooling
9 water intake structures. Basically calls for the
10 best cooling water intake technology.

11 At the present there have not been
12 regulations that dictated how it was done, and the
13 regional boards have dealt with it on a case-by-
14 case basis.

15 The USEPA has proposed regulations on
16 that which are fairly difficult to comply with, I
17 guess is the best way to put it. Basically it
18 would force the use of something other than once-
19 through cooling in all circumstances except where
20 the cooling water was drawn from the open ocean.
21 And this would only apply to new units or new
22 intake structures.

23 At this point it's a proposed
24 regulation. Because it falls under the basic
25 provision of all the federal regulations, they've

1 been held sort of in abeyance until the new
2 administration can move in and review what's being
3 done. So we don't know what will happen.

4 But the point being that if it were
5 instituted as it is, a new cooling water system
6 proposing to use once-through cooling, if it were
7 not located offshore in the open ocean, would
8 essentially be forced into something other than
9 once-through cooling.

10 In adopting the NPDES permit for a
11 discharge from a power plant, there are, of
12 course, requirements placed on all sorts of
13 pollutants that might be originating in the power
14 plant. They are generally not difficult to comply
15 with, but they do have to be addressed and the
16 region --

17 PRESIDING MEMBER LAURIE: Let me -- I'm
18 sorry, I'm thinking a little slowly this morning.
19 On the question of once-through cooling, --

20 MR. ANTON: Right.

21 PRESIDING MEMBER LAURIE: -- is that the
22 most commonly used technology today for gas fired
23 plants?

24 MR. ANTON: I believe it is, but
25 somebody from the Commission probably could answer

1 that.

2 MR. O'HAGAN: Probably in terms of
3 megawatts for our larger facilities, I would say
4 yes, and certainly older facilities. And that's
5 why we're seeing a lot of them being repowered.

6 Certainly in new generation from the
7 1970s on it has actually been cooling towers, wet
8 cooling. You know, I think probably Diablo Canyon
9 might have been the last once-through cooling
10 facility approved in the state -- the Moss Landing
11 repower certainly.

12 MR. ANTON: And so it's sort of an
13 interesting comparison if you look at the nuclear
14 plants that are operating. San Onofre uses a
15 system where it does draw from offshore and
16 discharges offshore. That's the type of a system
17 that under the proposed 316(b) regulations would
18 essentially be required.

19 Diablo Canyon, on the other hand, draws
20 from the shoreline. And under the proposed
21 regulations that would probably not be allowed,
22 because they sort of separate the locations and --

23 PRESIDING MEMBER LAURIE: So, can Diablo
24 do -- would they need to modify?

25 MR. ANTON: No. It applies to -- if the

1 regulations were promulgated as proposed, it
2 applies to new intake structures.

3 Now, again, looking at the water effects
4 of those two facilities, both of them have had
5 concerns raised about them. Diablo does heat
6 Diablo Cove, and based on my discussion with the
7 executive officer from the central coast region,
8 the biota of Diablo Cove has been altered by that
9 discharge, and basically changed to more of a warm
10 water situation. But I think that was expected
11 when it was permitted.

12 COMMISSIONER PERNELL: What about water
13 supply for inland plants?

14 MR. ANTON: Well, essentially if you're
15 talking about using a evaporative cooling system,
16 depending on the type of the power plant, they can
17 use a lot of water.

18 If that's the proposal, and the desire
19 to get a new water right, for instance, to take
20 water from a surface watercourse, that would take
21 a long time to obtain. Water rights are -- well,
22 much of the water is already used up, it's already
23 appropriate to others. And the process of getting
24 a water right, it's a long process.

25 If they would go to some other source,

1 for instance an irrigation district that might
2 already have a water right, and buy water from
3 them would be a better solution. That would fall
4 under the state board's policy, and they would
5 need to show that that was the most economically
6 and environmentally sound proposal to go with.

7 And, again, on the inland, if they use
8 evaporative cooling they would also have to worry
9 about disposal of the cooling tower blow-down.

10 COMMISSIONER PERNELL: And what happens
11 to that? I mean they would have to worry about
12 the disposal, but typically where does that go?

13 MR. ANTON: Well, if it's inland the
14 existing plants, or plants that were operating,
15 I'm thinking of Rancho Seco, they were required to
16 blow down a fairly large amount to keep the salt,
17 the salinity down.

18 On the other hand, if they were located,
19 for instance, in the desert and they might be
20 pushed to use as many cycles as possible,
21 concentrate the salts in the tower, and then
22 discharge a smaller amount of water to line the
23 evaporation ponds. So the salt would be protected
24 from the existing usable groundwater.

25 MR. O'HAGAN: If I can interject,

1 Commissioner, we have power plants that discharge
2 to evaporation ponds like Mr. Anton said. And we
3 have power plants that discharge to actually the
4 local sewer system.

5 We have facilities that inject the
6 wastewater into the groundwater through injection
7 wells. And we also have facilities that don't
8 have any wastewater discharge at all, zero
9 discharge facilities where the water is recycled
10 and, if you will, distilled off. And then that
11 leaves a solid cake of salts. And then the water,
12 which is fairly pure, is reused.

13 COMMISSIONER PERNELL: So it kind of
14 depends on the facility and the geographical
15 location as to what system is used?

16 MR. O'HAGAN: That's correct.

17 MR. ANTON: I think I've pretty much
18 covered what I initially wanted to say. Mr.
19 Wilson, do you have anything that you'd like to
20 add?

21 MR. WILSON: Yes, I have a few comments
22 to make. For the record my name is Craig Wilson;
23 I'm the Chief Counsel of the State Water Resources
24 Control Board. I'd like to thank you for giving
25 us an opportunity to speak this morning. Also

1 would like to give your staff some credit for
2 juggling the schedule to accommodate us.

3 I'll also talk really briefly, before we
4 get into some of the water issues, about a staff
5 memorandum of understanding that was entered into
6 between the Commission and the Board, I believe in
7 1998.

8 I can recall in the early '90s the
9 Commission Staff came over and asked us, you know,
10 maybe we need to have a memorandum of
11 understanding to kind of coordinate our
12 activities, making sure we're acting kind of on a
13 parallel basis, so things aren't delayed.

14 And we kept more or less saying, you
15 know, go away, there's not much happening in this
16 arena. We've got other things to do. And finally
17 I think they beat us into submission a little bit,
18 and we entered into this agreement.

19 And now it's a very, in retrospect, it's
20 very good that we have this, because I think it
21 does give us a process to try to coordinate our
22 activities and sort through some of these siting
23 issues as they relate to both water supply and
24 water quality. So, congratulations to your staff
25 for getting us to come into that.

1 PRESIDING MEMBER LAURIE: Well, peer art
2 does require patience, sometimes. Isn't that
3 right, Mr. --

4 (Laughter.)

5 PRESIDING MEMBER LAURIE: Thank you, Mr.
6 Wilson.

7 MR. WILSON: On the water issues, I
8 think there's kind of a parallel between the water
9 supply and the water quality in the sense that our
10 two major policies that deal with these issues
11 that the --

12 PRESIDING MEMBER LAURIE: Before you go
13 further, on the MOU, we've gotten great
14 cooperation from state agencies. Everybody is
15 under a lot of pressure to work in a timely
16 manner, and an effective manner in the approval
17 process, and state agencies have been terrific in
18 their cooperation.

19 So, I hope the intent behind that
20 agreement is working to the point where if we need
21 to talk about it again I would expect to hear
22 about that.

23 MR. WILSON: Absolutely. Again, the two
24 major policies that the state board adopted, and
25 these were both adopted in the early '70s, the

1 thermal plan which deals with water quality
2 issues; and then the cooling policy that deals
3 with mostly supply issues.

4 It's kind of interesting, they
5 established some very broad general policies, and
6 then there were not a lot of, you know, cases that
7 happened after that to actually implement and
8 flesh out the details and see how projects would
9 comply with the policies.

10 They're written pretty generally. They
11 both have some flexibility in them to, I think,
12 address, you know, the energy issues that are
13 present today. So it's just now, you know, 25
14 years after the fact, that we're really beginning
15 to have cases coming up, interpreting some of the
16 provisions in both of those policies.

17 I'll give you a couple of examples. On
18 the cooling water policy, which was adopted back
19 in 1975, there was a project up in Shasta County;
20 I believe it was called Three Mountain Power
21 Project, that raised some of the supply issues.
22 It originally came before our regional board
23 because it was an inland facility that the project
24 proposing use of water supply from groundwater,
25 and quite a bit of use of groundwater.

1 There was some water quality concerns
2 about the disposal of the blow-down wastes and
3 other things to the evaporation ponds.

4 But in the context of our regional board
5 considering those, some of the interested parties
6 to this project brought up this cooling water
7 policy, saying, you know, wait a minute. This
8 project's calling for large amounts of fresh
9 water, fresh groundwater to be used. And the
10 policy seems to state, you know, a preference that
11 that's about the last resort.

12 And ultimately there was basically a
13 settlement of that case. The parties got together
14 and the project was redesigned such that it
15 basically, you know, resulted in mostly a dry
16 cooling situation. Much much less use of
17 groundwater.

18 So, the policy worked in a sense to
19 bring the parties together to work out a proposal
20 that was satisfactory to everybody. I believe
21 that project was certified.

22 Regarding the water quality, I think Ed
23 handled those questions pretty well. I'll just
24 touch on a couple of things.

25 On the issue of the intake structures

1 and the proposed USEPA regulations, in case your
2 staff has not looked at them, they were proposed
3 in the August 10, 2000 issue of the Federal
4 Register. They are proposed regulations.

5 I believe the Bush Administration has
6 already put out an executive order basically
7 putting a hold on all proposed regulations, so
8 we're not sure exactly what might come out of
9 that. But if those regulations went forward
10 intact they could potentially be a fairly
11 significant constraint on new facilities, if the
12 intake structures were either to rivers or lakes
13 or to estuarine areas, because that's where the
14 most stringent requirements would apply.

15 Probably the most significant current
16 issue dealing with the water quality deals with
17 the thermal plan, and it relates to which
18 standards of the thermal plan applies to these
19 projects that are being repowered or modernized.
20 And I believe the Duke Energy representatives will
21 probably speak to this issue.

22 But it makes somewhat of a difference in
23 that when the thermal plan was adopted, certain
24 standards applied to new facilities and certain
25 standards applied to existing facilities which

1 were basically grandfathered in.

2 Even the new facilities, if something is
3 considered a new facility there is an exception to
4 the requirements that Mr. Anton talked about, and
5 that exception process was used in the Moss
6 Landing situation such that alternative limits to
7 the more stringent requirements were applied.

8 Other facilities, there could be a very
9 good case made that certain other facilities in
10 this modernization repowering are, in fact,
11 existing discharges rather than new discharges.
12 And we're kind of looking at these on a case-by-
13 case basis.

14 We're looking at the Morro Bay plant
15 right now to see in an overall sense whether the
16 plant, even though there's been some
17 modernization, you know, if the discharge place is
18 the same, the volume is pretty much the same,
19 there's probably some pretty good arguments to be
20 made that that could be considered an existing
21 discharge, and therefore subject to the
22 grandfathered limits.

23 But, again, I think we're going to have
24 to explore that on a case-by-case basis and make
25 determinations.

1 So, with that, I think I've completed
2 what I needed to say. Ed, do you have something?

3 MR. ANTON: Yes, there's one other thing
4 I wanted to mention. First of all, I forgot to
5 point out is that we are committed to cooperating
6 with you to make sure that the projects do move
7 ahead.

8 We recognize the urgency of the state's
9 power needs and the need to help alleviate that.
10 Recognizing all the constraints that we deal with,
11 as well.

12 PRESIDING MEMBER LAURIE: Some of the
13 various legislative proposals have us
14 communicating to various officialdom throughout
15 the land regarding any delay in our licensing
16 process. And so we hate to waste paper. And so
17 further cooperation is always a good thing to
18 think about.

19 MR. ANTON: One other thing I wanted to
20 mention about water supply, there is some
21 discussion in your staff draft about the use of
22 groundwater.

23 Ostensibly California doesn't regulate
24 the use of groundwater through a water rights
25 process. But there is a lot of water law and case

1 law that relates to the use of groundwater, and
2 probably the most significant thing is that if a
3 use of groundwater that uses a lot, and a power
4 plant can use a lot, might get in a case where it
5 would tend to take water away from other water
6 users of the same groundwater basin such that they
7 would want to basically litigate over what's
8 called correlative rights, and how the water is
9 shared among all the users of the groundwater.

10 It can also fall under the courts of
11 what might be considered an unreasonable use of
12 water if it would take too much from other water
13 users.

14 I only mention that to point out that
15 while it might look like groundwater might be
16 unrestricted in its use, it could be an impediment
17 if somebody proposes to use a lot of groundwater
18 in a basin where that might impact other people.

19 PRESIDING MEMBER LAURIE: How good are
20 we, and maybe some of our other folks are in a
21 better position to answer, at being able to
22 geographically define underground basins? Can we
23 do that with a great deal of skill?

24 MR. ANTON: Well, the fellow from
25 Department of Water Resources probably could

1 better answer that. But I believe most
2 groundwater basins are pretty well defined. At
3 least the ones that are major basins.

4 There are a lot of parts of the state
5 where the groundwater is not very well defined,
6 but those probably aren't basins that would have
7 sufficient capacity to provide water for something
8 like a power plant.

9 PRESIDING MEMBER LAURIE: Okay.

10 MR. ANTON: That's all I really have.

11 PRESIDING MEMBER LAURIE: Thank you.

12 Mr. Wilson, I should note that 7558 sought to be
13 litigated in our Pastoria case. The General
14 Counsel's office wrote an excellent memorandum in
15 defense of the Commission's actions in that
16 regard.

17 If you have not had an -- and the
18 litigated appeal was unsuccessful. So, to the
19 extent that our Mr. Chamberlain can share his memo
20 with you, it may be worth discussing.

21 MR. WILSON: We were familiar with that
22 issue, and I actually talked to Mr. Chamberlain
23 about that issue.

24 PRESIDING MEMBER LAURIE: Great, thank
25 you very much. Gentlemen, we appreciate your

1 time, thank you.

2 Mr. O'Hagan.

3 MR. O'HAGAN: Thank you, Commissioner.

4 I just want to quickly point out that Three
5 Mountain hasn't been certified, but it's getting
6 close.

7 Also, too, in terms of the groundwater
8 supply is that, as Mr. Anton indicated, most of
9 the groundwater basins have been fairly well
10 identified. There are some situations like we ran
11 into with once again the Three Mountain project,
12 where you have a fractured hard rock aquifer, and
13 it is really hard to define that.

14 And also the situation is that there
15 will be actually multiple aquifers in some
16 situations like we find in western Kern County,
17 where there's sort of a layer cake approach that,
18 you know, there may be several aquifers.

19 And so identifying the extent of those
20 and the interaction between the aquifers is often
21 quite difficult.

22 PRESIDING MEMBER LAURIE: Thank you.

23 COMMISSIONER PERNELL: Thank you,
24 gentlemen.

25 MR. O'HAGAN: I'd like to introduce

1 Kamyar Guivetchi from the Department of Water
2 Resources.

3 PRESIDING MEMBER LAURIE: Welcome, sir,
4 good morning.

5 MR. GUIVETCHI: Good morning,
6 Commissioner Laurie, Commissioner Pernell,
7 Commission Staff and the audience. I'm pleased to
8 be here. My name is Kamyar Guivetchi. I'm with
9 the Statewide Planning Branch of the Department of
10 Water Resources. I've been at that position since
11 last November and I look forward to this
12 opportunity to come before your Commission and
13 certainly share information regarding water and
14 energy, which seem to --

15 PRESIDING MEMBER LAURIE: What were you
16 doing before last November?

17 MR. GUIVETCHI: I was with the
18 Department's Suisun Marsh mitigation program, and
19 prior to that Delta planning and modeling.

20 PRESIDING MEMBER LAURIE: Great.
21 Pleased to have you here.

22 MR. GUIVETCHI: Maybe before I jump into
23 my presentation on the issue of groundwater basins
24 I will note that the Department is currently
25 undertaking the update of California's

1 groundwater, or otherwise known as bulletin 118.
2 The last update of that was in 1980. The next
3 update, and a final update will come out in 2002.

4 However, we are right in the middle of
5 developing a lot of that information which touches
6 on looking at the over 500 basins and sub-basins,
7 what their delineations are and how they can be
8 characterized with the best data that we have.

9 And I would offer that if Commission
10 Staff are interested, we can, at the staff level,
11 begin sharing that information with you and
12 hopefully provide you whatever resources that we
13 have that you need to do your planning.

14 PRESIDING MEMBER LAURIE: I deeply
15 appreciate it, thank you. Before you start I have
16 to admit to a gross lack of expertise on
17 underground water law.

18 I assume that law has been firmly
19 established in California for 100-plus years. Is
20 it fluid? Is it moving? Is it changing? Or do
21 you have any sense of any of that?

22 MR. GUIVETCHI: I think the short answer
23 is all the above. It depends on the basin and the
24 aquifer. I am not a groundwater specialist. The
25 other thing that I have, good fortune, is I do

1 have a staff specialist here today, Doug Osugi --
2 Doug, raise your hand, please.

3 He is our program project manager on
4 updating the bulletin 118. Doug, do you want to
5 try to address that?

6 COMMISSIONER PERNELL: Would you come
7 forward, please.

8 PRESIDING MEMBER LAURIE: Could you use
9 the microphone, sir. And give us your name,
10 please.

11 MR. OSUGI: Yes. My name is Douglas
12 Osugi. And I'm the Program Manager for the update
13 of bulletin 118, California's groundwater. And
14 right now we're in the middle of like having our
15 separate pairing. A lot of the information that's
16 going to go into the update were aligned primarily
17 on existing data that is now available, you know,
18 since 20 years.

19 We have a draft map of the groundwater
20 basins on our website that can be viewed, and we
21 ask for comments from water agencies and such, and
22 the public can send us comments on those basins.

23 We're in the process of characterizing
24 those basins in terms of some basic
25 geohydrological characteristics regarding water

1 budget information on them, as much as we can,
2 extraction data, and those types of things.

3 So we hope to get a published report out
4 in 2002 looking for a draft of the report sometime
5 this fall, a public draft. And we plan on having
6 workshops, public workshops to be able to explain
7 the bulletin draft at that time.

8 PRESIDING MEMBER LAURIE: I'm not going
9 to ask for a discourse on groundwater law, but
10 just in summary, if you have an aquifer that
11 serves multiple ownerships, what's the rights and
12 obligations of the parties?

13 Is use unlimited? Can you use it, but
14 not waste it? Is it first come, first served? Do
15 you have any thoughts about that?

16 MR. OSUGI: Well, normally, you know,
17 I'm not, like I said, I'm not an attorney on
18 groundwater law, but my understanding is that it
19 depends on where you are, in what basin. Of
20 course, if you have an adjudicated basin,
21 basically the water has already been spoken for if
22 it's gone through the court in that way, with a
23 court-appointed watermaster.

24 If it's not in an adjudicated basin,
25 then generally yes, it's really a first come,

1 first served where the state board is not involved
2 in that. It's usually left in terms of the local
3 entities, the planning departments, to determine
4 whether or not there's adequate water supply or
5 groundwater supplies in the area.

6 The problem we're finding now through
7 the bulletin 118 process and what's been known is
8 that there's so much lack of information on the
9 actual available and safe yield of some of these
10 basins. So that's one of the things that were
11 probably going to be part of Kamyar's presentation
12 is that in terms of the enormous amounts of
13 groundwater that could be used by these projects,
14 they'd have to work with -- I suggest that they
15 work with the local entities in the overall
16 planning process in terms of competing uses for
17 groundwater, as such.

18 And also protecting the resource in
19 terms of recharge and those kinds of things. And
20 as far as the disposal wastewater.

21 PRESIDING MEMBER LAURIE: Very good,
22 thank you, sir. We appreciate your comments very
23 much.

24 COMMISSIONER PERNELL: Thank you.

25 MR. GUIVETCHI: The only thing I would

1 add to that, and I'll touch on it later, is I
2 believe the law is the owner of the overlying land
3 essentially has access to the groundwater.

4 But I think there is an increasing
5 recognition, both by groundwater users in their
6 basins, and the Legislature, to encourage
7 groundwater basin management planning so that
8 while there's not a firm regulatory process on it,
9 they are trying to get the locals to be more
10 mindful of managing their basins efficiently.

11 PRESIDING MEMBER LAURIE: Okay, thank
12 you.

13 MR. GUIVETCHI: I do have a
14 presentation. Rick has promised to work --

15 PRESIDING MEMBER LAURIE: Well, I wish
16 you well.

17 (Laughter.)

18 MR. GUIVETCHI: Actually, I think we've
19 got to go, Rick, if you could hit the slide number
20 one. I think you're toward the end.

21 Okay, I think we can start on the next
22 slide. What I'd like to do first is I'd like to
23 put this in the context, the information I'm going
24 to present. I was asked to talk somewhat on near-
25 term, long-term, water supply availability.

1 Certainly it's in relation to your interest in
2 siting future power plants.

3 A number of people in the Department of
4 Water Resources were provided copies of your staff
5 paper on water supply; reviewed it. And all in
6 all we feel that it's a very well framed, well
7 written document.

8 The one editorial, I think there's a
9 typo on page 3 in conjunction with the current
10 average delivery of the State Water Project. It
11 states it's 2.1 million acrefeet. I believe it's
12 3.1 million acrefeet. So just for that to be
13 accurate.

14 What I will try to do is, as I'm making
15 my presentation, identify the numbers that are in
16 your staff paper to kind of show how they tie into
17 our overall water picture for California.

18 The information I'm going to present to
19 you is by and large what was put out as the
20 update, the 1998 update to the California water
21 plan.

22 The original, or first water plan, came
23 out in 1957. There have been numerous updates
24 since then. We are now in a five-year update
25 cycle. The last two were in 1993 and 1998. And

1 at the end of this presentation I'll give you a
2 little bit more flavor about how we're planning to
3 update the next one by 2003.

4 The plan is a master or strategic plan.
5 And it's in the water code. DWR is responsible
6 for putting out that plan, with input from water
7 purveyors, users and suppliers throughout the
8 state.

9 It does not have any implementation
10 teeth. It's made clear in the water code that
11 whatever is in the plan can only be implemented
12 after additional appropriations and authorizations
13 by the Legislature.

14 So, again it's a --

15 PRESIDING MEMBER LAURIE: Do you have to
16 do an EIR on that plan?

17 MR. GUIVETCHI: No, we don't do an EIR
18 because it is considered like a master or
19 strategic plan. It is not an implementation plan.

20 COMMISSIONER PERNELL: You said it has
21 to be approved by the Legislature?

22 MR. GUIVETCHI: No. My point was that
23 if any of the recommendations in the plan were to
24 be implemented, those actions would need
25 additional approvals by the Legislature. And

1 would have to go through an environmental review
2 process on a site-specific basis.

3 So, this is again a very over-arching
4 master or strategic plan. And basically the
5 approach has been up to now to do an inventory of
6 water supply, developed water supply in the state,
7 water uses in the state, and show how those
8 balance out. And if there are shortages in
9 regions and in time. Different hydrologic
10 conditions. And that's what I hope to share with
11 you today.

12 So, basically we'll look at supplies
13 uses. We'll look at a water budget with existing
14 facilities and projects. Also kind of forecast
15 into the year 2020 with what things might look
16 with projects or actions that were deemed highly
17 likely during the last process to update the water
18 plan.

19 I'll also end up by touching on a few of
20 the groundwater issues which I think we've already
21 touched on. Also, the cost of water was one of
22 your interests, or staff interests. And then I'll
23 end up with a few recommendations.

24 Next, please, Rick.

25 PRESIDING MEMBER LAURIE: Will you be

1 able to provide hard copies of your slides for us?

2 MR. GUIVETCHI: I certainly will. We
3 will provide electronic -- in fact, Rick has the
4 electronic copy, Rick Buell. And those could be
5 printed. I'll leave that file with Rick.

6 Did you want the copies right now?

7 COMMISSIONER PERNELL: No.

8 MR. GUIVETCHI: Okay. The purpose of
9 this pie chart is to bring home an important
10 point, and that is that the water plan and the
11 water budget data that are reflected in your staff
12 paper and are in the water plan don't cover or
13 consider all the water that falls on the state
14 through precipitation.

15 The large pie chart there represents
16 about 200 million acrefeet in an average
17 precipitation year. The two slices that have been
18 moved to the side, those represent the surface
19 runoff from that 200,000 acrefeet, which is
20 roughly 71 million acrefeet. And the dark shaded
21 pie is that portion which we call the developed
22 water supply, and includes some groundwater, which
23 is what's considered in or has been considered in
24 the California water plan update, and is the basis
25 of the data that I will present to you. And it

1 represents about 57 million acrefeet.

2 So, the point here is it's not -- the
3 supply and budget analysis that I'm going to
4 present to you does not mean it includes every
5 drop of water that falls on the State of
6 California. It's considered to be that developed
7 water supply that could be used for different uses
8 at this time.

9 And what I will show is how that
10 developed supply is then going to be, or is used,
11 or separated into urban, agriculture and
12 environmental uses.

13 Next slide, please. This is something
14 we all know and it's just a point that the bar
15 charts on the left are the average annual
16 precipitation that fall in the different regions
17 of the state.

18 We've separated the state into ten
19 regions, each bar chart represents the average
20 total precip that falls in that region. And as we
21 all know, most of the precip and runoff occur in
22 the northern part of the state versus the southern
23 part of the state.

24 What this is to show is that the total
25 pie chart in the previous is all the water of that

1 57 million acrefeet -- excuse me, 71 million
2 acrefeet. And this shows how it's distributed
3 throughout the state.

4 Next slide, please. We also know that
5 in time there's quite a bit of variability. And
6 this is all of the precip that fell in Januaries
7 over the last number of years, and the faint,
8 thin, horizontal line that you see there, that's
9 the average.

10 So those pie charts that I was showing
11 you, again, is for average conditions. And what
12 we see is from year to year the average precip can
13 vary quite dramatically both below and above the
14 average.

15 Next slide, please. The ten regions
16 here, we've kind of separated them out like a
17 puzzle and the arrows that you see going between
18 those regions, and the thickness of those arrows,
19 are to show current water movement from one region
20 to another.

21 And the numbers aren't so much important
22 as the fact that while we get precip in these
23 regions and we presented them that way, it in no
24 way means that the water remains in those regions.
25 In fact, through both natural courses, water

1 courses, and human-made water courses, the water
2 can be conveyed to other regions.

3 Now, an important thing -- a footnote to
4 this is this is the capacity of water that can
5 move. It doesn't mean that we could always move
6 this much water whenever we want. There are
7 regulatory, environmental conditions and
8 constraints that will sometimes preclude being
9 able to move this much water anytime that we
10 desire.

11 PRESIDING MEMBER LAURIE: Those are
12 simply physical and engineering constraints, it
13 can be done?

14 MR. GUIVETCHI: Yes. This shows you the
15 physical capacity for doing it.

16 PRESIDING MEMBER LAURIE: Okay, and --

17 MR. GUIVETCHI: Not the whether you
18 could do it at any instant in time, moment in
19 time.

20 PRESIDING MEMBER LAURIE: -- when you
21 earlier mentioned the 200 million acrefeet that
22 has not been utilized as part of our water system,
23 how much of that would be feasible to develop if
24 public policy demanded that it be done?

25 So, if a water emergency were declared

1 and somebody said we need to get more water on
2 line. We have 200 million out there that's not
3 being utilized, feasibly how much of that would be
4 available for development, absent other public
5 policy questions?

6 MR. GUIVETCHI: Okay, one clarification.
7 The entire pie was 200 million acrefeet --

8 PRESIDING MEMBER LAURIE: I see, okay.

9 MR. GUIVETCHI: We are using, of that,
10 71 million acrefeet of surface runoff, and of
11 that, 57 million acrefeet of the total 200 is what
12 we consider the developed water supply.

13 Toward the end of my presentation you
14 will see our projections of likely projects that
15 could occur by the year 2020 that either through
16 demand reduction or supply augmentation could
17 increase water supplies in the order of a couple
18 million acrefeet.

19 But, again, that's kind of still within
20 that developed water supply wedge. Up to now we
21 have not really actively considered moving into
22 the smaller creeks which were the other runoffs,
23 or the larger area which is just waterfalls and
24 surface runoff where it percolates into
25 groundwater.

1 I guess the theoretical question would
2 be from an engineering point of view we can do a
3 lot of things, but there are a lot of interests,
4 concern that we don't want to adversely affect the
5 environment in doing so.

6 So it's that delicate balance that we're
7 going to have to look at.

8 Okay, next, please. This slide, it's a
9 little difficult to read, but the point here to
10 make was that of the total supply that we have,
11 which is, if you notice, 77.9 million acrefeet, is
12 that 78 million acrefeet which is in your staff's
13 white paper or water supply paper.

14 So it's broken up by surface water
15 contribution, groundwater contribution, recycled
16 and desalted water. Of the surface water
17 contributions a part of that is managed by the
18 Central Valley Project, Colorado River Project and
19 other federal projects, a part by the State Water
20 Project.

21 Of the federal and state projects
22 together, that only accounts for about 30 percent
23 of the surface water resources, or the water
24 supply, excuse me.

25 The point here is not that the state and

1 federal water projects are not important; in fact,
2 they are because of their storage and conveyance
3 facilities and flexibility.

4 But the other -- what I'm really trying
5 to point out is a lot of the water is controlled
6 at the local level, which could be what you're
7 going to be concerned with when you're looking at
8 siting power plants.

9 So, 70 percent of the water supply is
10 actually controlled at the local level. Not by
11 the state and federal water projects.

12 And we see, of the total 78 million
13 acrefeet of water supply, this is average again,
14 average conditions, about 12.5 million acrefeet
15 come from groundwater and about 300,000 acrefeet
16 come from recycled and desalted water.

17 Next slide, please. This slide is that
18 same total, about 78 million acrefeet, but just
19 showing how it's distributed regionally amongst
20 those ten geographic regions. And, again, this is
21 pretty self evident.

22 Next slide, please. This slide, what
23 I'd like to do is first draw your attention to the
24 pie chart on the lower left. This is the existing
25 or what was considered the 95 base conditions in

1 the last update of the water plan.

2 And of that wedge, that dark wedge that
3 is being considered in the water plan, this shows
4 how it's distributed between urban, ag and
5 environmental water uses. And what you'll see is
6 that the urban -- excuse me, the agriculture and
7 the environment are roughly the same, around 45
8 percent. And the urban around 11 percent of the
9 total use.

10 So, --

11 PRESIDING MEMBER LAURIE: And what's
12 included in the category of environmental?

13 MR. GUIVETCHI: Okay, that's a good
14 point. Again, because we're only considering the
15 wedge that's the developed water, this includes
16 the wild and scenic rivers, instream uses, and
17 water uses for refuges.

18 So it doesn't mean all the water that's
19 used by the environment in California, because, as
20 you noted, a large part of that large pie we don't
21 even consider because it's not developed water.

22 So these are the waters that are running
23 through developed water courses through the state,
24 and can either -- which are either wild and
25 scenic, or have some instream minimum water

1 requirements for protecting the aquatic habitat,
2 or are diverted to feed managed wetlands refuges.

3 Now, we've kind of shifted gears now.
4 We went from supplies, and now we're looking at
5 uses of that supply. The pie chart on the lower
6 right is our projection of what things might look
7 in 2020.

8 And what you'll note there, the numbers
9 don't change appreciably, but there's a slight
10 shift predicted from agriculture to urban. As
11 population increases and ag lands are developed,
12 the total distribution will change slightly from
13 agriculture to urban.

14 Next slide, please.

15 COMMISSIONER PERNELL: Well, let me ask
16 you a question on that.

17 MR. GUIVETCHI: Please.

18 COMMISSIONER PERNELL: Does that
19 represent that in the last five years and the next
20 20 years that the environmental water allotment
21 won't change?

22 MR. GUIVETCHI: What this suggests is if
23 '95 was considered as the base year when the last
24 update was done, and 2020 was the planning
25 horizon, that for the developed water slice of the

1 pie it was estimated that the needs of the wild
2 and scenic rivers, instream uses, and uses on
3 refuges would not change appreciably, that's
4 correct.

5 COMMISSIONER PERNELL: Okay, and --

6 MR. GUIVETCHI: That's the assumption.

7 COMMISSIONER PERNELL: Okay.

8 MR. GUIVETCHI: Next slide, please.

9 What we'd like to do now, we've talked about
10 supplies, we talked about uses, we're now looking
11 at budgets.

12 And so we're putting the two together.
13 We have in the upper part of the table water use,
14 again split by urban, ag, environmental total.
15 These are the same numbers that were on those pie
16 charts on the previous slide.

17 And then on the lower part of the table
18 you have supplies which are surface water,
19 groundwater, recycled and desalted, which is again
20 a summary of the slides a few slides ago.

21 And we see that in our estimates for the
22 1995 level of development or base condition in an
23 average hydrologic water year, those are a lot of
24 caveats, that the shortage between the uses and
25 the supplies was about 1.6 million acrefeet.

1 Now the footnote here is that much of
2 that 1.6 million acrefeet was groundwater
3 overdraft. Okay.

4 Now, the column to the right is the same
5 analysis, but again for the projected planning
6 horizon of 2020, and what you'll see is that the
7 supplies don't change appreciably. But because
8 we're assuming that population increases, the
9 urban water use goes up, ag water use actually we
10 assume would go slightly down, because if you
11 recall we're assuming some ag lands will go out of
12 production, and environmental water use stayed
13 pretty much the same.

14 So that now, the new balance, because we
15 have more uses and about the same supply with our
16 existing facilities and programs, our shortage or
17 shortfall we assume is about 2.4 million acrefeet.
18 And that value, again, was in your staff's white
19 paper.

20 Next slide, please. This is the ten
21 regions again, and there are two sets of numbers.
22 The blue numbers on top for each region are the
23 average conditions, which is what we've been
24 talking about. And what this is intended to show
25 is of that total shortage of 2.4 million acrefeet

1 projected for 2020, how would that show up
2 regionally.

3 And what it shows is except for the
4 Tulare Lake and the north Lahontan, all the others
5 basically would not have -- I'm sorry. What this
6 shows is that the shortage -- I was thinking of
7 future programs, we'll get to -- what this shows
8 is that the shortage is distributed quite
9 differently throughout the regions of the state.

10 And again, because uses are tied to
11 population and agricultural production and
12 supplies generally are on the northern part of the
13 state.

14 Next slide, please. Okay, now we'll
15 shift and say what we did in the water plan is say
16 by the year 2020 what options for additional
17 demand reduction or supply augmentations might go
18 into effect that could change the water balance.

19 And I'm not going to go into detail
20 here, but essentially we're assuming -- we assumed
21 that about a half a million acrefeet could be
22 gained by reducing demands through water
23 conservation, recycling, reclamation.

24 We looked at or assumed that we could
25 increase local supplies, surface water,

1 groundwater and maybe to your interest, you see
2 that we estimate that there's going to be a
3 significant increase in recycling and desalting
4 water.

5 And because of the ability of power
6 plants to use these waters, there might be an
7 opportunity, even in the future, to tap in on
8 these waters as the state board policy suggests,
9 rather than looking for fresh water.

10 Because one of the things the CalFed
11 process, and all water planning processes are
12 emphasizing is really stress demand management up
13 front, and then look for supply augmentation.

14 Now, that demand management, to the
15 extent it results in recycling, may be a source of
16 water that could be available for power plant
17 siting.

18 PRESIDING MEMBER LAURIE: One policy
19 issue that is going to come up in discussion of
20 the use of desalinized water, I assume when you
21 talk about the use of such you're talking about
22 coastal use, is that right?

23 MR. GUIVETCHI: You're absolutely
24 correct on the desalinization side. I was really
25 emphasizing the recycling and reclamation side.

1 Because there the energy issue is not the same.
2 And it's not kind of limited to coastal uses,
3 you're absolutely right.

4 PRESIDING MEMBER LAURIE: Because the
5 point being that, and it may even be true when you
6 get to recycling, the use of recycled water or
7 desalinated water suggests new power plant uses in
8 heavily urbanized and coastal areas.

9 Well, there's other barriers to siting
10 plants in urbanized and coastal areas. And so
11 there will be increasing pressures to locate
12 plants outside of these areas where such resources
13 are not going to be available. So there is going
14 to be conflicts.

15 MR. GUIVETCHI: Your point is very well
16 taken. I'll just add, Commissioner Laurie, that a
17 lot of the availability for drain water, reclaimed
18 drain water does come from agriculture. So there
19 could be less populated areas where there will be
20 opportunities for reclaimed water through
21 drainage.

22 And essentially, the bottomline of this
23 slide shows that of the total options either
24 through reducing demand or increasing supplies, we
25 could look at about 2.2 million acrefeet by the

1 year 2020.

2 Next slide, please. Now, if we take
3 that and overlay it to what we had talked about
4 with our existing programs and options, in this
5 slide the 1995 column are the same numbers.
6 They're there just for reference.

7 But you'll see that the 2020 numbers
8 have now, the water uses have reduced somewhat,
9 particularly on the urban side. And the water
10 supply has been increased, so that rather than 2.4
11 million acrefeet shortage, we're now to about .2
12 million acrefeet shortage.

13 Next slide, please. And this is that
14 same slide which I confused with the earlier one,
15 showing that with these likely options in the year
16 2020, there would only be a couple of the ten
17 regions that in an average water year may still
18 have shortages.

19 The thing to note, though, that on each
20 of those regions there's also a red number below
21 the blue number, that is for a dry water year
22 condition which I haven't really spent a lot of
23 time talking about. But it does show that in
24 those years there still could be some significant
25 shortages.

1 Next slide, please. I'm now going to
2 turn my attention to the issue of cost. In the
3 water plan we haven't spent a lot of time or focus
4 on water costs, but in the '93 update we did do a
5 survey of what industrial water costs were by
6 region on a per acrefoot basis.

7 And, again, it's kind of hard to read at
8 that scale, but what you'll see is the wide
9 variability of costs, anywhere from about \$10 to
10 \$15 an acrefoot in Fresno to as much as about
11 \$1600 an acrefoot in Santa Barbara. And that's
12 probably because of the desalinization option
13 there.

14 Okay, next slide, please.

15 PRESIDING MEMBER LAURIE: On the
16 question of the use of the environmental waters, I
17 would guess that the regulatory scheme that
18 provides for the use of such waters are a
19 combination of both state and federal, is that
20 right? Or is it mostly federal, or is it mostly
21 state?

22 MR. GUIVETCHI: You mean the regulatory
23 aspect of it?

24 PRESIDING MEMBER LAURIE: Yes.

25 MR. GUIVETCHI: They're both --

1 PRESIDING MEMBER LAURIE: Okay, and some
2 fall under federal jurisdiction and some fall
3 under state jurisdiction.

4 From a state perspective, to what extent
5 do regulators view the -- I forgot what the
6 numbers were -- 37 million acrefeet, no, or is
7 that percentage -- how many million acrefeet are
8 set aside for environmental use?

9 MR. GUIVETCHI: It was about 45 percent
10 of the 57 million acrefeet.

11 PRESIDING MEMBER LAURIE: To what extent
12 do you folks view that as a reserve? So that in
13 cases of emergencies or extreme drought conditions
14 or earthquakes or whatever, the rules could be
15 modified for use of that water for either urban or
16 agriculture.

17 Do the rules allow that? Who has
18 jurisdiction? Do courts have jurisdiction? Does
19 Congress have jurisdiction? Who ultimately
20 controls the use of those waters?

21 MR. GUIVETCHI: You're treading on the
22 periphery of my expertise. That might be a better
23 question to ask the State Board --

24 PRESIDING MEMBER LAURIE: That's never
25 stopped me, so feel free.

1 MR. GUIVETCHI: -- but to the extent
2 that I have been involved in environmental review
3 processes and permitting processes, generally
4 environmental permits or environmental components
5 of permits do not have an emergency provision in
6 them.

7 What has happened, for instance when
8 we've had major floods where levees have been
9 damaged and we've had to go in and do emergency
10 work, we've had to request an emergency review by
11 the regulatory agency and authorization to do that
12 work.

13 In some instances the Governor, like
14 during the 1997 and 1998 floods, did provide some
15 state level waivers for those conditions, but from
16 the U.S. Fish and Wildlife Service, and even Fish
17 and Game from the state perspective, we would go
18 to them, and it's very prudent to go to them and
19 work with them during the emergency, and say that
20 these are the things we have to do, and we need
21 your assistance to give us the permission to do
22 it.

23 But it is on a -- to the extent that I
24 know, on a case-by-case basis.

25 Okay, next slide, please. This is a

1 slide that shows the cost of pumping groundwater,
2 again cost per acrefeet. And there are more bar
3 charts, because what it shows is for each of those
4 ten regions it shows a low and a high.

5 And, again, for instance on the north
6 coast you can see groundwater pumping rates vary
7 from \$10 an acrefoot to about \$50 an acrefoot.
8 And it can go as high as \$130 an acrefoot in the
9 San Francisco Bay region and elsewhere.

10 So, again, electrical power costs for
11 doing groundwater extraction differ depending on
12 where you are.

13 Okay, next slide. This we kind of
14 touched on a little bit. And this is the idea
15 that while there are no regulations like we have
16 on surface water, for groundwater there is an
17 increased trend for groundwater basin users to
18 work together to have management plans.

19 And this will work into one of my
20 recommendations for this Commission. AB-3030 has
21 worked to set up about 150 of those, and about 17
22 counties have already enacted groundwater
23 management ordinances since '94.

24 So what this indicates is that as
25 sitings for future power plants are looked at, it

1 would be very good to work closely with the local
2 entities, especially if they have groundwater
3 management plans and ordinances.

4 COMMISSIONER PERNELL: Are those
5 groundwater ordinances typically the same? Or do
6 they vary widely between counties?

7 MR. GUIVETCHI: I believe they vary
8 widely. Doug, do you have any input on that?
9 Yeah, are the ordinances very different from
10 county to county?

11 MR. OSUGI: Generally the ordinances --
12 just a little background on those ordinances that
13 have occurred since 1994, a lot of them have to do
14 with being implemented over concerns about
15 potential export of their groundwater to outside
16 the county area.

17 So a lot of the ordinances have
18 provisions in there, conditional use permit type
19 language that require anyone that wants to export
20 groundwater out of the county to make sure that
21 there are no negative or adverse impacts to the
22 local area.

23 And that's kind of what's driving a lot
24 of the implementation of these ordinances there.
25 But the management plans have been going on for

1 quite some time, and does show that there's a lot
2 of interest in the management of the resources by
3 the local entities.

4 MR. GUIVETCHI: Rick, can we have the
5 next slide? I think it goes right into -- this is
6 a map of the state and, again, I don't expect you
7 to see all the detail, but an important thing is
8 the yellow dots, which are primarily in the
9 southern part of the state, those are adjudicated
10 basins and --

11 PRESIDING MEMBER LAURIE: Adjudicated by
12 whom?

13 MR. GUIVETCHI: By the courts. So at
14 some point a court stepped in and worked with the
15 locals on how the waters would be used and
16 distributed --

17 PRESIDING MEMBER LAURIE: And that would
18 have been the result of a petition filed by one
19 owner when there's a contest?

20 MR. GUIVETCHI: Could be many different
21 scenarios, but the point being is that in those
22 cases if a power plant were going to be sited,
23 there would be a much more formal process to get
24 the ability to use the water, because it has been
25 adjudicated.

1 The other dots that are there are these
2 areas where ordinances have been set up and water
3 management plans occur. And, again, those can be
4 opportunities because what it could mean is if the
5 people that are looking to develop or build the
6 power plants set up early communication with the
7 local basin managers, that they could find
8 potentially a win/win. Especially through the
9 reclaimed water aspect of it.

10 Next slide, please. Now, just a few
11 overarching recommendations. I will have to note
12 that the State Board Resolution 7558, while
13 several years old, believe, still has a lot of
14 insight and application by giving us some guidance
15 on looking at using kind of the water conservation
16 approach first, and then using the surface water
17 or the fresh waters to the least extent possible.

18 And so I think that, as a guideline, is
19 probably still a very good approach to consider in
20 future siting of power plants.

21 The second bullet is unfortunately in
22 the last few water plan updates we haven't worked
23 closely with Commission Staff on looking at the
24 nexus between energy and water. And I think as of
25 late it's become very clear that there is a nexus,

1 an important nexus.

2 And my recommendation is we need to, and
3 I'll do my part, to work very closely with your
4 staff to insure that the next update takes into
5 consideration as many of these options and
6 opportunities that we can.

7 It's a two-sided coin, because not only
8 as we've been talking today, future sitings of
9 plants may have a water supply impact, but some of
10 the water conservation measures have an energy
11 impact.

12 And so what we'll want to do is to try
13 to find as few cases where we're hurting each
14 resource by trying to help the other.

15 The third bullet is there's been a lot
16 of effort by CalFed to help fix the delta, and
17 many of the actions that CalFed is planning to do
18 doesn't occur within the delta proper, but
19 throughout the central valley and the southern
20 water delivery service area of the state.

21 And one thing to be mindful is to make
22 sure that future sitings of power plants in some
23 way doesn't exacerbate those actions that are
24 trying to fix the delta and other aspects of state
25 water and environment.

1 And then finally, it's this idea that
2 I've mentioned a few times, is it would be very
3 prudent, especially on the groundwater level, but
4 also because locals manage 70 percent of the
5 state's developed water supply, to work very early
6 and in a coordinated fashion with local managers,
7 water management districts, in trying to plan and
8 find opportunities for the power plant sitings.

9 And then just a few slides -- next
10 slide, please, is to emphasize that we are in the
11 next update of the water plan. And that we are
12 approaching this in a much new and different
13 fashion, partly because it's been required by new
14 legislation that's modified the water code, and
15 partly because I think we, as a Department, also
16 believe that this is the best way to go.

17 We are striving for a much more
18 collaborative consensus-based process with broad
19 public input. And having an open, transparent
20 process where we can share our assumptions, data
21 and methodology with people as we're going along
22 during the update process.

23 We have a public advisory committee
24 that's close to 60 people with agency, water
25 purveyors and a broad cross-section of water

1 interests in California. And we also have an
2 extended review forum that is between 100 and 200
3 people so far, who will also help us in this
4 process.

5 And, again, I would hope that the
6 Commission Staff becomes more engaged with us in
7 this process.

8 Next slide, please. The timetable is by
9 the end of this year we have to put out a roadmap
10 of what our methodology and assumptions are. By
11 early 2003 we will have to have a draft plan out
12 that will go out for public comment and review.

13 And by the end of 2003 we will have the
14 next update for the California water plan
15 distributed.

16 And then the last slide, this is kind of
17 just a flavor of things to come. If you notice in
18 all the maps prior that I showed you they had ten
19 large regions. When we do our data crunching
20 they're actually done in these things called data
21 analysis units. There are 275 or so in the state.
22 Much more specificity in spatial definition.

23 And so what we hope to do is make the
24 water balances that are done at that level readily
25 available to people that would need them. And so

1 if you're going to be siting power plants, that
2 kind of information would be more useful than if
3 you're getting data for a much larger area.

4 That concludes my presentation.

5 PRESIDING MEMBER LAURIE: And very
6 nicely done. Question for you. And I'm going to
7 ask for Bill Chamberlain's help on this. Bill,
8 can I get you to a microphone.

9 On any individual project that comes
10 before us, and we're doing our water analysis, and
11 the question is, is there a significant impact.
12 And that question would especially arise if the
13 issue is contested.

14 You've indicated that I think 70 percent
15 of available water is under the control of local
16 jurisdictions. What is your understanding of what
17 environmental data we should be using to determine
18 whether or not the proposed project significantly
19 impacts the water supply?

20 Am I framing the question
21 satisfactorily, Bill?

22 MR. CHAMBERLAIN: Well, I'm not sure if
23 I understood the question, so --

24 PRESIDING MEMBER LAURIE: Well, let me
25 try it again. We're in area X and it's clear that

1 there's some debate among the community as to
2 where and how this water should be utilized. Over
3 here wants it to be used 4000 acrefeet for the
4 plant, the group over here wants to build a new
5 community at the edge of the old community. And
6 they argue that this 4000 acrefeet significantly
7 impacts water supply.

8 What environmental documentation is
9 available that allows us to say no, we have these
10 documents, and these documents clearly indicate
11 that there's no significant impact on the water
12 supply?

13 It can't be the state water plan,
14 because the state water plan doesn't have any
15 environmental documentation attached to it.

16 Do the local districts, in adopting
17 their plans, do environmental analysis that can be
18 relied on?

19 MR. GUIVETCHI: I believe for their
20 general plans, no. I think any city/county plan
21 also is exempt from CEQA/NEPA because again it's
22 not -- there's no implementation aspect.

23 One area that you could look to is
24 CalFed certainly has done a lot of rigorous
25 environmental review and analysis for the areas

1 that it is concerned with, which would be the
2 central valley and the southern water service area
3 in California.

4 So, there are a lot of environmental
5 review and documentations in areas that are the
6 purview of CalFed.

7 I think any of these local water
8 districts at some point will have done or would
9 have to have done some kind of action that would
10 require environmental documentation. So a good
11 place to start, again this is going back to early
12 communication with the locals, to contact them,
13 find out what they've done, what information they
14 have, what environmental documents they have
15 produced.

16 I don't think there's any overall recipe
17 or cookbook that you could use because I think the
18 issues, the environmental issues will be very
19 different depending on the site-specific
20 conditions that you're going to be confronted with
21 for any particular plant.

22 But I think there is a lot of
23 information out there, and I would start with the
24 people in the area that you plan to do the
25 project, or proposing to do a project.

1 One thing that I didn't put up as a
2 recommendation, but I think it's -- I'll add,
3 anyway, is that it does look, from your staff
4 paper, that you do have quite a bit of a range of
5 technologies and flexibilities.

6 And one thing that you may want to
7 consider, because of the highly variable water
8 conditions in the state, between wet and dry, is
9 provide yourself those options.

10 So options are combined wet/dry cooling
11 options. What it does, when there's water you
12 would use the wet side. And when we're in a dry
13 period, drought year, rather than needing 2000 to
14 4000 acrefeet per year, you would fall down to the
15 60 to 200 acrefeet.

16 And so what it does, it gives your
17 project proponents a lot of flexibility to weather
18 those dynamic swings in California water. And
19 that isn't going to change. We have a very
20 spatially and in time variable precipitation
21 pattern and runoff pattern.

22 So anything that you can do that can
23 give you robust flexibility at any one plant would
24 be helpful.

25 MR. O'HAGAN: If I can respond to the

1 question, too, Commissioner Laurie. General
2 plans, updates, revisions do generally trigger a
3 CEQA requirement. And also in terms of water
4 district, they're required to do a master plan
5 periodically. And there is a CEQA document
6 associated with that.

7 And taking the High Desert Power Project
8 as a case in point, Victor Valley Water District
9 did do a master plan and a CEQA document.
10 However, it was sort of a broad-brush, and dealt
11 mainly with growth inducing and infrastructure
12 requirements.

13 And working on the case the main concern
14 there, of course, was the groundwater pumping
15 effects on the Mojave River and endangered
16 species, which was not addressed by that document.

17 However, the Commission did rely on the
18 Victor Valley CEQA document in terms of addressing
19 growth-inducing impacts from the project.

20 PRESIDING MEMBER LAURIE: So, are we --
21 this is a question: In almost all cases is there
22 environmental documentation available, having been
23 done by other entities, that we can rely on?

24 MR. O'HAGAN: No. And the case in point
25 because --

1 PRESIDING MEMBER LAURIE: Did you say
2 no?

3 MR. O'HAGAN: Yes.

4 PRESIDING MEMBER LAURIE: Yes.

5 (Laughter.)

6 MR. O'HAGAN: In many cases there's
7 specific, taking groundwater as an example,
8 hydrogeologic information and things. But in
9 terms of doing well draw-down analysis, how the
10 groundwater pumping is going to affect,
11 contaminate groundwater, whether that's going to
12 draw that to somebody else's drinking water well
13 and things, generally we don't have that
14 information.

15 And that's one of the big time
16 constraints that we face, is collecting that
17 information, doing the analysis. It's a lot of
18 information, it's very complex issues generally,
19 and it takes quite awhile.

20 And then I think sometimes you do see
21 delays in the siting process because of that
22 analysis.

23 PRESIDING MEMBER LAURIE: Thank you.

24 Bill, did you have any additional thoughts on that
25 question?

1 MR. CHAMBERLAIN: Yes. I think one of
2 the recommendations that you heard this morning
3 was that we need to work more on the overlap
4 between energy needs and water needs, because one
5 of the things that we saw in the High Desert
6 Project was -- or actually in some of these
7 projects we've seen people making the contention
8 that use of water is a waste when you're using it
9 for evaporative cooling.

10 And we found that if you just looked at
11 the prices that we were seeing last summer for
12 power, and looked at the efficiency penalty that
13 dry cooling would have imposed, particularly on a
14 plant in the desert, we were getting just enormous
15 value for the 4000 acrefeet of water that was
16 being employed there.

17 And you notice that when he put up the
18 costs of water, some areas the cost of water is
19 very low, and in other areas it's very high.

20 In this case I believe probably the
21 value of water for cooling in that particular case
22 was higher than any of those figures that were put
23 up this morning.

24 PRESIDING MEMBER LAURIE: Thank you.
25 Joe.

1 MR. O'HAGAN: Another point I'd like to
2 bring out is that even though, and I could use
3 High Desert as an example again, is that there are
4 a number of adjudicating groundwater basins in the
5 state, that generally those adjudicated basins
6 there's really not a constraint on new groundwater
7 development.

8 The situation with High Desert would be
9 that even though it's been adjudicated, there's
10 obviously been a lot of litigation associated with
11 that. The project, there was no constraint on
12 them putting in new wells to serve the power
13 plant.

14 A number of the ordinances that we've
15 dealt with for siting cases where the county has
16 requirements in terms of wells, it's not also a
17 constraint on groundwater pumping, just often it's
18 their way of keeping tabs on what wells are going
19 on and how much is being pumped, and specifically
20 looking at public health concerns of the
21 groundwater.

22 Our next speakers are Wayne Hoffman and
23 Brian Waters of Duke Energy. They're going to
24 talk about once-through cooling and cooling
25 alternatives.

1 PRESIDING MEMBER LAURIE: Good morning,
2 gentlemen.

3 MR. HOFFMAN: Good morning,
4 Commissioners Laurie and Pernell. Thank you for
5 the opportunity to be here today. My name's Wayne
6 Hoffman and I'm Regional Environmental Manager for
7 Duke Energy North America. To my right is Brian
8 Waters with Duke Engineering and Services, one of
9 our lead water consultants.

10 I feel like I may be talking about the
11 wrong subject after all this discussion about
12 inland water supply, but I would point out while
13 I'll be focusing on the issue of coastal power
14 plants, and water quality and water issues related
15 to once-through cooling in my presentation, a
16 number of issues have come up here today that deal
17 with the question of water supply generally as it
18 relates to inland power plants.

19 And I'd like to just take a minute or
20 two at the end of my presentation to address a few
21 of the questions which we have been exploring
22 options on. And therefore, I would not like
23 anyone to assume that the emphasis being put on
24 ocean-cooling and once-through cooling in this
25 presentation in any way is intended to preclude

1 the value or the future relevance of using fresh
2 water in inland plants.

3 I think that there are a number of
4 issues that need to be looked at, and I'll talk
5 about this briefly following this presentation.

6 So, Rick, whenever you're ready. You
7 can go to the second slide. I'm wondering if you
8 may need to take it out of that holder. I didn't
9 realize how much glare it was going to cause, but
10 it looks like it may work better.

11 (Off-the-record conversations for
12 technical adjustments.)

13 MR. HOFFMAN: Do the Commissioners have
14 a hard copy of this?

15 PRESIDING MEMBER LAURIE: Yes.

16 MR. BUELL: There are hard copies on the
17 table as you come in, if you would like to get a
18 copy.

19 MR. HOFFMAN: This first slide addresses
20 kind of the energy profile as it relates to the
21 presence of once-through cooling systems in the
22 state now, and is directly responsive to an
23 earlier question of yours, Commissioner Laurie.

24 About 40 percent of the state's
25 generation is now once-through cooling. About 8

1 percent of that total is nuclear. And most of
2 those plants, about 20,000 megawatts worth, are
3 intaking and discharging directly on the coast.

4 There are several plants, about five or
5 six -- close to 5000 or 6000 megawatts which are
6 now being proposed, or in the case of Moss
7 Landing, under construction, utilizing these type
8 of systems.

9 And with this 20,000 megawatts in the
10 fairly extensive sites with currently existing
11 intake and discharge structures with currently
12 available gas supply and electric transmission
13 structures, transmission systems, the repowering
14 or expansion of capacity on these sites could
15 provide a substantial amount of the future demand
16 for the State of California.

17 And as you'll see on one of my late
18 slides, that once-through cooling process is
19 extremely efficient relative to other projects.
20 One analysis that we did on a 1000 megawatt
21 project shows that you lose close to 100 megawatts
22 when you go from a once-through cooling system to
23 a dry cooling. Referencing Mr. Chamberlain's
24 earlier remarks.

25 I would also point out a couple existing

1 state policies of the California Coastal
2 Commission in the Coastal Act now prioritize the
3 value of coastal dependent industry giving some
4 preference and priority to using these existing
5 plants.

6 The State Water Resource Board policy
7 sets a priority for power plant cooling water
8 uses. And the highest priority is given to ocean
9 water for cooling, next to wastewater which is
10 discharged to the ocean.

11 Just a quick, this next slide --

12 COMMISSIONER PERNELL: Can I stop you
13 here before we go to the next slide, --

14 MR. HOFFMAN: Yes.

15 COMMISSIONER PERNELL: You indicated
16 that had gone from a wet system or once-through
17 system to a dry cooling, you lose about 100
18 megawatts of efficiency?

19 MR. HOFFMAN: On a 1000 megawatt plant.

20 COMMISSIONER PERNELL: On a 1000. So,
21 we talked earlier about there is water basins, and
22 if we had a situation that's inland with a
23 depleted water basin, the probability of an
24 applicant wanting to site a plant there is, in
25 your opinion, --

1 MR. HOFFMAN: Very low.

2 COMMISSIONER PERNELL: -- very low. And
3 it's because of --

4 MR. HOFFMAN: I think, and I'll talk
5 about that --

6 COMMISSIONER PERNELL: -- the water
7 issue?

8 MR. HOFFMAN: -- more later, but, as Joe
9 indicated before, it will have a lot to do with
10 the adjudication existing in that water basin,
11 with the available supply, the cost, the potential
12 for tradeoff with state water, the availability of
13 groundwater, all those issues.

14 The next slide. Generally these
15 modernized or repowered plants offer a lot of
16 benefits, most of which we presented in the case
17 of Moss Landing; including considerable reduction
18 in the use of sea water because of the 30 to 40
19 percent increase in efficiency; usually a
20 reduction in the flow, which I'll talk about in a
21 minute; reduction in air emissions; reduction in
22 the use of natural gas which in this market is of
23 extreme importance to the ratepayers, and will
24 have a major effect on the future cost of power
25 supplies in this state.

1 We have the capability of producing a
2 much quieter plant, covering a much smaller
3 footprint, with reduced marine impacts. And we
4 can avoid a lot of construction impacts typical of
5 a greenfield site.

6 The smaller profile of these plants, you
7 know, at Morro Bay, for example, we're taking down
8 a plant that's 165 feet high and has three stacks
9 450 feet tall, and replacing it with a plant
10 which, for the most part, is less than 50 feet
11 tall and has stacks of 145 feet.

12 There are a couple, the heat recovery
13 steam generators on that plant that approach, I
14 think, 90 feet. But for the most part, that
15 plant's profile is a lot smaller. Particularly an
16 important issue along the coast.

17 Typically these plants will result in
18 considerable improvement in coastal access and
19 dealing with coastal related environmental issues.

20 The modern plants also provide -- next
21 slide, Rick -- a number of marine and water
22 biology impacts. One of the examples that we use
23 in a plant that we're proposing before the
24 Commission now results in reduction in annual
25 flows of close to 40 percent; reduction in

1 impingement and entrainment as a result of those
2 reductions in flows.

3 An annual cooling water flow per
4 kilowatt hour reduction of over 40 percent. And a
5 reduction in temperature of the water decreased
6 and the heat load of almost 40 percent reduction
7 to the receiving waters. And the total heat load
8 reduction on a per kilowatt hour is more than 40
9 percent.

10 Next slide, please. As I implied
11 before, the repowering of an existing site
12 preserves and expands the most efficient form of
13 energy production we have today.

14 I would point out there are people who
15 are raising a lot of questions about the exchange
16 of these new plants, or the use of these new
17 plants in lieu of letting the existing plants run,
18 and I would just point out that in this
19 environment, and it looks for the foreseeable
20 future, Morro Bay for example, the existing plant,
21 it has run more in the last year than it has run
22 in the last 15 years.

23 And the emissions from that plant, the
24 water demand from the plant are considerably
25 higher than the proposed facility which will

1 increase production of energy in megawatts by
2 about 20 percent.

3 So, the reuse of existing sites and
4 replacing existing plants is a major positive
5 environmental effect. And I think that one could
6 go so far as to call it a demand side management
7 tool in the sense that you're using the fuel far
8 more efficiently than you would be otherwise.

9 These plants, the use of them results,
10 as I mentioned, in decreased coastal environmental
11 impacts. If we can avoid using cooling towers on
12 the coast I think that's very important from a
13 visual standpoint because of the size and the
14 unsightliness of cooling towers. Not to say that
15 there aren't appropriate places for them. And the
16 noise associated with these, as I mentioned
17 before, is also a factor.

18 Next slide. The counsel for the State
19 Water Board, Craig Wilson, spoke briefly to the
20 issue of what is happening at the state level with
21 respect to existing versus new discharges, and how
22 this might be handled.

23 This is an extremely important issue to
24 those generators in the State of California who
25 are looking at repowering of these existing sites.

1 And I would just point out that from the two
2 regulatory issues which drive the water issues at
3 a coastal plant using once-through cooling are
4 federal regulations which were referenced by Mr.
5 Anton and Mr. Wilson.

6 These are called section 316(a) which
7 has to do with the thermal discharge of a power
8 plant, and section 316(b). And I will talk about
9 those a little bit here.

10 This slide references the issue of
11 existing versus new discharge. And although Mr.
12 Anton pointed out that it's difficult to evaluate
13 in the short term the thermal effects of a power
14 plant, I would argue, and will make the point
15 here, that most of these plants have extensive
16 data available about both the thermal discharge
17 and the effects of the intakes. Some less
18 thorough than others, but there is information out
19 there.

20 And we believe, particularly on the
21 thermal side, short-term studies in the range of
22 60 to 90 days, in some cases, doing thermal
23 overflights and temperature recorders in the
24 water, can enable a developer to come up with an
25 extremely accurate profile using mathematical

1 modeling of what is going to be happening with the
2 plume, the thermal plume, and what the predicted
3 biological effects might be of that discharge
4 based on historical knowledge and the technology
5 that we have today to predict what will happen
6 with this thermal discharge.

7 So, the issue that we're facing today,
8 and reference was made to the federal regulations,
9 I'd like to address that briefly, although it's
10 not in my presentation.

11 We have submitted over 300 pages of
12 comments through a group called the Utility Water
13 Action Group in Washington, D.C. on these federal
14 316(b) regs. And our strong position with that
15 proposed set of regs for EPA, which is currently
16 on new facilities, is that a facility being
17 repowered on an existing site in California does
18 not constitute a new facility.

19 And that we can use the existing
20 discharge and intake systems without major
21 modification, and thereby qualify as an existing
22 facility, and thereby, under the 316(a)
23 regulation, enable us to operate under the
24 approach which Mr. Wilson described before, of
25 meeting the requirements, we call them the BIC

1 requirements, the requirements that a balanced,
2 indigenous community of the populations of the
3 fish and shellfish, et cetera, be maintained in
4 that biological environment.

5 This is --

6 PRESIDING MEMBER LAURIE: Mr. Hoffman,
7 in your papers that you're referring to, what are
8 you using as a definition of repower?

9 MR. HOFFMAN: Well, probably the term
10 modernize would be a better term. This might vary
11 from case to case, but it would certainly, for
12 example, in the case of Moss Landing it involved
13 the replacement of 600 megawatts that had been
14 shut down previously by PG&E, and the installation
15 of over 1000 megawatts which then operate in
16 conjunction with the existing operating 1500
17 megawatt plant, which is there now.

18 PRESIDING MEMBER LAURIE: So you, in
19 your papers you have not defined the term repower
20 or to modernize?

21 MR. HOFFMAN: Other than to say that it
22 involves the reuse of existing discharge and
23 intake facilities at an existing power plant site.

24 In Morro Bay we're going to take down
25 the entire old plant and replace it and use the

1 existing discharge and intake facility.

2 COMMISSIONER PERNELL: If you take down
3 an old facility and construct a new one, as long
4 as you're using, in your scenario, as long as
5 you're using the intake and discharge apparatus
6 for the plant, you're categorizing that as
7 repowering?

8 MR. HOFFMAN: That's correct.

9 COMMISSIONER PERNELL: Even though you
10 got a new facility?

11 MR. HOFFMAN: I don't know that the term
12 repowering has particular legal meaning in this
13 context, so -- I think that the term of
14 significance in the federal regs is is it a new
15 facility or an existing facility.

16 And there are definitions in the Clean
17 Water Act which relate to that, and which need to
18 be complied with. And since I'm not a lawyer, I
19 can't give you a clear explanation of that.

20 But we're using the term repowering and
21 modernization somewhat interchangeably here.

22 COMMISSIONER PERNELL: Right, but --
23 well, please continue.

24 MR. HOFFMAN: Okay. I would point out
25 one thing about the thermal regulations under

1 316(a). If you are defined as a new discharge,
2 the challenge, and I think the issue that we all
3 might face in terms of how can we expedite power
4 plant development and protect the environment, is
5 that the new discharge requirements are that you
6 meet a 20 degree temperature difference between
7 your intake and your discharge -- I'm sorry,
8 between the discharge and the receiving waters,
9 where you're discharging.

10 You also have a requirement to meet, in
11 the ocean, anyway, a four degree difference
12 between your discharge and the receiving water at
13 1000 feet.

14 These parameters are somewhat arbitrary.
15 In fact, in discussions with a Regional Water
16 Board member recently, I was told the four degree
17 figure was arrived at not based on any scientific
18 studies which indicated that this parameter was
19 one which protected species, but that it was, in
20 fact, the lowest temperature they could measure
21 and make the differential.

22 So, the point here is you can get
23 tangled up in long-term studies of highly detailed
24 nature trying to demonstrate these distinctions
25 when, in fact, under the existing discharge

1 definition you have to meet the same marine
2 biological protective parameter of protecting the
3 balanced indigenous communities. And then you
4 don't get tangled up in that. And I think that's
5 an important point.

6 We would also argue that these
7 replacement plants can usually meet the
8 requirement that there be no adverse material
9 change in the discharge in order to qualify for
10 this existing discharge classification.

11 Morro Bay is a good example. We'll be
12 lowering the temperature, lowering the overall
13 heat load over time, and we'll be lowering not
14 only the intake volume going through the plant,
15 but we will significantly slow the down the
16 velocity of water coming into that plant, and
17 thereby reduce the number of species of fish that
18 are caught on the traveling screens that screen
19 out anything coming into the plant.

20 PRESIDING MEMBER LAURIE: I think we're
21 going to start getting some dirty looks from our
22 general counsel if we continue to make reference
23 to existing projects.

24 (Laughter.)

25 PRESIDING MEMBER LAURIE: So, attempt to

1 speak as generically as we possibly can.

2 MR. HOFFMAN: Okay. I forgot that
3 admonition prior to this. Thank you for the
4 reminder.

5 On the next slide, Rick, we'll talk
6 briefly about the 316(b) process which regulates
7 the intake. I would point out that the federal
8 regulations are already set up to expedite the
9 process. And by this I mean that the CEC has what
10 seems to be, based on our experience of working
11 with the staff and the regional water boards, a
12 very effective memorandum of understanding for
13 working together.

14 And that the driving force behind these
15 water analyses is the NPDES permit process under
16 the Clean Water Act, which is handled by the
17 regional water board.

18 I think the processes we've worked in
19 the past have worked pretty well. I think we're
20 all looking for ways to help streamline those. We
21 believe that if we can present adequate
22 information up front, and that we can demonstrate
23 that we're not increasing impacts from what one
24 might reasonably assume to be a baseline of an
25 existing plant, and in this condition I would, you

1 know, maybe make a distinction between different
2 facilities without mentioning names.

3 But that there are facilities where
4 there's clearly a case if a plant's being taken
5 down or being taken out of use, that there's an
6 established baseline from that plant's operation.
7 And that the new plant will then be compared
8 against that.

9 There may be situations where if the old
10 plant continues to operate one would look at it
11 slightly differently.

12 I would point out that the existing
13 plants using once-through cooling water systems
14 have, as I mentioned before, extensive studies
15 that can often be confirmed in a reasonably short
16 period of time.

17 And we would recommend both that
18 extensive reliance be made on these studies, and
19 that up front it be determined what is necessary
20 to be done in order to, you know, achieve a
21 confirmation that might have been determined in a
22 previous NPDES permit that a) the facility is in
23 compliance with the BIC requirements of beneficial
24 indigenous species protection; and also that it
25 meet what they call BTA, or best technology

1 available, for minimizing adverse environmental
2 effects from the intake from impingement and
3 entrainment.

4 PRESIDING MEMBER LAURIE: From a
5 developer's perspective, is it your view that the
6 federal requirements, as set forth in 316(a) and
7 (b), with proper engineering, can be met?

8 MR. HOFFMAN: Yes.

9 PRESIDING MEMBER LAURIE: Thank you.

10 MR. HOFFMAN: I think we are somewhat
11 concerned about the new proposed regs, however,
12 because they, as counsel mentioned, could cause
13 some fairly severe changes in the process.

14 PRESIDING MEMBER LAURIE: Thank you.

15 COMMISSIONER PERNELL: Just from a
16 regulatory standpoint, the California Coastal
17 Commission is an entity that you would have to go
18 through in order to construct a plant on the
19 California coast?

20 MR. HOFFMAN: Would you rather answer
21 that, Joe?

22 MR. O'HAGAN: No, I'll defer to you.

23 (Laughter.)

24 MR. HOFFMAN: The California Coastal
25 Commission, under the Coastal Act, has the

1 authority to determine whether or not a project,
2 at least this is my understanding, is consistent
3 with the Coastal Act.

4 It will make recommendations through the
5 Warren Alquist Act process that the Energy
6 Commission uses, and in general its determinations
7 or assumptions are required to be followed by the
8 Energy Commission.

9 There may be conditions under which the
10 Energy Commission determines that a Coastal
11 Commission proposal is either infeasible or less
12 environmentally sound than what they, or in this
13 case, perhaps, the water board is proposing. And
14 they may therefore stay with their own approach.

15 COMMISSIONER PERNELL: Right. And then
16 there's a federal requirement that you have to
17 adhere to, as well, which is what we're talking
18 about here, the 316 --

19 MR. HOFFMAN: Yeah, this 316(a) and (b)
20 are implemented by the Regional Water Board, and
21 with certain circumstances that counsel mentioned
22 before, where there's an exception being requested
23 to the thermal side of it going up to the State
24 Board for concurrence.

25 But, as far as 316(a) and (b) are

1 concerned specifically, it's my understanding
2 that's not the responsibility of the Coastal
3 Commission.

4 The Coastal Commission has its own
5 regulations and interpretations as it relates to
6 water quality. And it will impose those.

7 COMMISSIONER PERNELL: Right. I guess
8 what I'm not understanding is what role does the
9 federal government play in --

10 MR. HOFFMAN: Oh, I'm sorry. The
11 federal government has, as I understand it, chosen
12 similar to EPA on the Clean Air Act, delegate it
13 down to the regional water boards through the
14 State Water Board, the authority to implement
15 316(a) and (b).

16 COMMISSIONER PERNELL: Thank you.

17 MR. HOFFMAN: Next slide. I think that
18 we've covered this adequately. So let's go to the
19 next slide.

20 Well, this one I'll explain to you
21 briefly by taking out all the yeses and noes and
22 putting little checkmarks in there, makes it a
23 little bit easier.

24 Across the top line, this is a
25 comparison of cooling system advantages and

1 disadvantages compared to once-through cooling.

2 On the top left is the harbor intake
3 ocean discharge. And across the top there are the
4 categories that increase marine impacts, increased
5 air emissions, increased visual, noise, land use,
6 construction, capital cost and efficiency.

7 And if you were to put in an ocean
8 intake in a cooling system you would have a lot
9 more increased impacts for a variety of reasons,
10 which I won't go into.

11 Similar on an ocean discharge. You
12 would have increased land use effects,
13 construction impacts, capital costs and efficiency
14 hits.

15 If you use cooling ponds, the third from
16 the bottom there, as part of the cooling system
17 you have considerably higher impacts, as you do
18 with cooling towers. And I think from the
19 Commission's experience with inland plants using
20 fresh water and cooling towers, you're aware of
21 the PM10 emission issues associated with those.
22 They obviously cause a greater visual impact and
23 there is some noise associated with them. They
24 take up more land and they have greater
25 construction impacts.

1 The air cooling is of a similar nature,
2 although the emissions don't increase. You have
3 tremendous efficiency hits. And a number of other
4 direct effects.

5 Next slide. This next slide shows the
6 comparison from an efficiency standpoint. The
7 next two. And I'll explain this.

8 The once-through cooling, if it were
9 considered the standard, in comparison, and this
10 is for a 1000 megawatt plant, a natural draft
11 cooling tower which one might think of a nuclear,
12 the big concrete towers as an example of that.
13 You would lose about 48 megawatts on a 1000
14 megawatt plant in efficiency.

15 And a mechanical draft cooling tower,
16 typical of many of the inland plants being built
17 with fresh water, you have about a 5 percent loss,
18 or 50 megawatts on 1000. And on an air cooled
19 system, up to 100 megawatts.

20 And as it's mentioned at the bottom of
21 the slide, the reduced efficiency will be replaced
22 by other generating units which will be in
23 general, until the entire, you know, fleet in
24 California is replaced, more expensive and higher
25 polluting.

1 PRESIDING MEMBER LAURIE: And would you
2 agree that efficiency is one of many factors that
3 we need to examine? For example, when you look at
4 these four alternatives, they might all look
5 different in physical appearance, so that
6 depending upon the community you're in what it
7 looks like may make a difference.

8 Water availability in the geographical
9 area may make a difference. Cost of water in a
10 geographical area may make a difference.

11 So, if I were to write down that
12 efficiency is an important, but only one of the
13 criteria that needs to be examined, when you're
14 looking at which alternative to utilize, would you
15 agree with that statement or not?

16 MR. HOFFMAN: No, I would agree with
17 that. I think there are obviously situations
18 where different systems are more appropriate, even
19 given the efficiency hit.

20 I think we're, you know, given that
21 we've got gas prices today that are several times
22 what they were a year ago, we're a lot more
23 sensitive to this.

24 PRESIDING MEMBER LAURIE: Can you go
25 into cost differentials? Are you going to talk

1 about --

2 MR. HOFFMAN: Yes, let's take a look at
3 the next slide. That's exactly what that is. And
4 unfortunately, like everything else we're looking
5 at today, it's going to be hard to read.

6 But the numbers on the left, since you
7 can't read them, the lowest one is 100 million,
8 200 million, 300, it goes in hundred-million-
9 dollar increments.

10 The blue bar on the chart shows the
11 difference, comparing over 30 years of operation,
12 the cost of mechanical cooling, natural draft
13 cooling, and air cooling with different gas
14 prices.

15 So the blue bar shows that with a
16 mechanical cooling, which is a fairly typical
17 multi-tower fresh water cooling system, you're hit
18 on the power plant cost of producing power over 30
19 years would be about \$130 million. With gas at
20 \$3.50 an mmBtu at about --

21 PRESIDING MEMBER LAURIE: Is this again
22 for a 1000 megawatt plant?

23 MR. HOFFMAN: This is for a 1000
24 megawatt, yeah. And for \$5 mmBtu gas, which is
25 probably where gas will settle back into,

1 somewhere in that range, perhaps a little less,
2 you have about a \$200 million hit.

3 And then you go over to the right and
4 you see the air cooled, where over the cost of --
5 over a 30 year term there's almost a half-billion-
6 dollar increase in the cost of that power over 30
7 years, with a \$5 mmBtu cost.

8 Now that cost would triple to a billion-
9 and-a-half dollars at today's prices. Now, nobody
10 expects to see gas stay at today's prices, but
11 just as an indicator.

12 COMMISSIONER PERNELL: This chart
13 doesn't reflect the construction costs of the
14 plant, just the operation and maintenance costs?

15 MR. HOFFMAN: Quite right, and it also
16 doesn't connect the O&M -- doesn't incorporate
17 either the O&M costs or the increased construction
18 costs.

19 PRESIDING MEMBER LAURIE: If I were to
20 be crass, and I'm only saying this because Mr.
21 Tomashefsky to my left asked me to ask this
22 question, otherwise I certainly --

23 (Laughter.)

24 PRESIDING MEMBER LAURIE: Let's say, as
25 regulators, we could care less how much your

1 operation is, except to the extent that it affects
2 the consumer, and the price that the consumer pays
3 for your product.

4 So are you able to -- or what would we
5 have to do to use the data in this slide to figure
6 out what the cost to the consumer would be, or the
7 additional increased costs of the various systems?

8 Are we able to do that by manipulating
9 numbers?

10 MR. HOFFMAN: Yeah, well, yeah, we could
11 do it fairly easily, although my mathematical mind
12 is not capable of doing it right here. We could
13 figure out fairly reasonably the total megawatt
14 hours produced over the life of this plant, and
15 come up with a cost per kilowatt hour pretty
16 easily. And we'll be glad to provide those
17 numbers to the Commission.

18 PRESIDING MEMBER LAURIE: If you could
19 do that would be very helpful.

20 MR. HOFFMAN: Yeah, I will make sure I
21 get that to Mr. Buell, and that he gets it
22 forwarded to you.

23 And we'll also provide in that table
24 some numbers on how O&M and construction costs
25 would factor into it.

1 COMMISSIONER PERNELL: That would be
2 helpful.

3 MR. HOFFMAN: The last slide here is
4 just kind of a summary. I think that from the
5 standpoint of water process and evaluating the
6 water factors we are concerned about certainty
7 associated with schedule.

8 It is very difficult to know whether or
9 not we can meet a year-long or a six-month
10 schedule when we enter it without certainty. So
11 timetables and standards of what we need and how
12 we're going to approach it are very important.

13 As I mentioned before, focusing on
14 existing studies and data and confirmatory studies
15 are important.

16 And we would just make a recommendation
17 that when a replacement plant or modernization
18 lowers the water use, reduces biological effects
19 from an existing baseline plan, that this project
20 should be able to move forward without mitigation
21 requirements.

22 I thank the Commission for this
23 opportunity to present this, and I'd just like to
24 make a couple comments about the fresh water
25 issue, because it was discussed in such detail.

1 Commissioner Laurie, in response to your
2 question about groundwater adjudication, I'd point
3 out that we're also looking at some opportunities
4 in the inland areas.

5 And in areas where groundwater is not
6 adjudicated, our understanding is that a general
7 rule of thumb, or rule of law, is that a landowner
8 can draw groundwater to the extent that he's not
9 impacting on his neighbor's supply. And this is
10 sort of a common law approach to it.

11 And there are a number of basins in
12 California where there are pretty substantial
13 groundwater supplies. And I think that these
14 areas where there is not adjudication, and one of
15 the reasons there isn't is these farmers who are
16 there prefer to avoid it at all costs.

17 And I think the solution to the fresh
18 water problem may lie in, and this will remain to
19 be seen as we move forward with proposals, in a
20 creative process that involves the agriculture
21 community, that attempts to balance the use of
22 groundwater with such approaches as water banking,
23 recharging the aquifer, a tradeoff of groundwater
24 with water project water, and a number of creative
25 approaches that in the end will have agricultural

1 benefits in that, in some cases, the farmers can
2 use less water-demanding crops, they can improve
3 the quality and protection of the land from
4 salting-up, from high use of fertilizer and
5 irrigation over time.

6 It can provide the farmers with income.
7 It can provide opportunities for lower cost power.
8 I think that was a very interesting chart that the
9 gentlemen from DWR put up showing the considerable
10 cost to some farmers for the cost of pumping. It
11 can be 30, 40 percent of the cost of the water, to
12 pump, just for the electricity.

13 So I would just point those things out.
14 And, also, I don't think very much emphasis was
15 put on this, but we believe strongly that you can
16 virtually eliminate the discharge issue associated
17 with these cooling towers and inland water plants
18 through zero liquid discharge systems, which a)
19 enable you to considerably increase the efficiency
20 and the use of water in a power plant; and result
21 in no discharge and no Aaron Brockovich problems.
22 And, you know, we all like to stay away from
23 those. And not have to use filtration ponds.

24 The solid discharges are generally
25 nontoxic and can be disposed of in a reasonable

1 manner.

2 COMMISSIONER PERNELL: Is that a fairly
3 new technology, or has that been around?

4 MR. HOFFMAN: I think that it isn't real
5 new, but the creation of these systems at a cost
6 effective level is somewhat new. And I think that
7 there are systems out there now which can be
8 reasonably incorporated.

9 One of the challenges is finding water
10 which has a quality which doesn't cost a fortune
11 to build the system for it, and removing, for
12 example, suspended solids. But they are
13 definitely available.

14 In fact, if I'm not mistaken, one of the
15 plants that has been approved already uses this
16 system, in southern California.

17 MR. O'HAGAN: Several of our projects
18 have been certified to use zero discharge, and
19 with a drop in cost of like reverse osmosis and
20 alternate filtration and things like that. It's
21 turned out to be a lot more cost effective
22 technology to use than it was 10, 15 years ago,
23 though it was available then.

24 MR. HOFFMAN: Thank you for the
25 opportunity. That's all I have.

1 COMMISSIONER PERNELL: Well, thank you
2 for your presentation. It was very informative.

3 PRESIDING MEMBER LAURIE: On the
4 question of groundwater, again, when you all are
5 looking for potential sites, the benefit of
6 finding an adjudicated basin is that you know what
7 the rules are going to be. And either you're
8 allowed or either you're not allowed.

9 But if you're out in the more rural
10 areas of the state where perhaps there is not
11 adjudication, and let's say it's agricultural, and
12 you propose to take a 30-acre parcel that's
13 currently utilized for agriculture, and utilize it
14 for power plant purposes, I think the water use is
15 greater for the power plant than it would be for
16 30 acres of agriculture, right?

17 MR. HOFFMAN: Obviously, yes;
18 considerably greater.

19 PRESIDING MEMBER LAURIE: Do you stay
20 away from those circumstances because of the
21 potential of litigation over the use of those
22 basins, or do you at least check it out to see if
23 there's going to be some kind of deal that you can
24 work? Or do you just remove those from your list
25 of possibilities?

1 MR. HOFFMAN: Well, it's a very complex
2 answer, but I'll use an example in another state
3 to respond to it. Where in a desert situation we
4 literally purchased thousands of acres to secure a
5 water right for a power plant and we also restored
6 most of that land that we bought to natural
7 conditions and maintained an open space. That was
8 one way to get the water right.

9 We would be less likely to do that in
10 California in an already developed agricultural
11 region because of the increased costs.

12 But as I alluded to before I would just
13 say that it's going to take some creative effort
14 in working with the agricultural community in
15 trying to find ways to use the power plant
16 presence to a) reduce their costs of production
17 and provide them with benefits; assist them in
18 implementing and I think, hopefully I won't offend
19 anyone, but I think many people in the room are
20 aware that the greatest opportunity for
21 conservation in California may be in the
22 irrigation systems, installing drip irrigation,
23 and the cost of that may be offset by benefits
24 that the farmer might get from working with the
25 power plant developer.

1 So, that, and you know, being creative
2 about how groundwater is used through recharge,
3 through banking, through exchanges, those are all
4 approaches that are being looked at.

5 PRESIDING MEMBER LAURIE: Excellent,
6 thank you.

7 At this time I think we want to go
8 to -- we want to provide an opportunity for
9 questions or comments on panel member comments?
10 Is that what we want to do, Mr. O'Hagan?

11 MR. O'HAGAN: Yes.

12 PRESIDING MEMBER LAURIE: I think so.
13 Okay. So, let's provide that opportunity. Ladies
14 and gentlemen, for those of you wishing to comment
15 or ask questions on these specific presentations
16 please feel free to do so at this time.

17 If not, then we will thank the panelists
18 for your outstanding presentations and we will see
19 you back here at approximately 1:20 for a
20 continuation of the program.

21 Thank you very much.

22 (Whereupon, at 12:15 p.m., the workshop
23 was adjourned, to reconvene at 1:20
24 p.m., this same day.)

25 --o0o--

1 AFTERNOON SESSION

2 1:23 p.m.

3 MR. O'HAGAN: Briefly, sort of a recap
4 of this morning's discussion, I think there was a
5 number of issues raised regarding water supply and
6 water regulations in California. As was pointed
7 out there's a diverse number of local, state and
8 federal water regulations that come into play, and
9 there's obviously a lot of options for water
10 supply for power generation.

11 This afternoon's discussions are going
12 to deal with technological solutions. We have two
13 consultants here that are Mike DiFilippo on my
14 left and John Maulbetsch on my right. They are
15 consultants working for the California Energy
16 Commission right now under the PIER program.

17 Mike is looking at the use of degraded
18 water and cooling towers. And John is looking at
19 dry cooling.

20 So, without further adieu. Oh, John's
21 first? I'm sorry.

22 MR. DiFILIPPO: The agenda says John's
23 first.

24 (Laughter.)

25 MR. O'HAGAN: Okay, John's first, my

1 apologies.

2 PRESIDING MEMBER LAURIE: 'Afternoon,
3 sir.

4 DR. MAULBETSCH: Commissioner Laurie,
5 it's good to see you again. The last time you and
6 I were in a room talking about dry cooling was a
7 couple months ago when Det Kroeger was here from
8 South Africa.

9 PRESIDING MEMBER LAURIE: Correct.

10 DR. MAULBETSCH: And he gave some
11 general background on the history of dry cooling.
12 And what I'd like to do today is become a little
13 more quantitative and a little bit -- get behind
14 some of the things he said and explain a little
15 bit about why they may be true.

16 PRESIDING MEMBER LAURIE: Thank you.

17 DR. MAULBETSCH: The first slide, if we
18 could, Rick. Just to calibrate ourselves, I'm
19 going to be talking largely in terms of the kind
20 of power plants that are currently being
21 considered and being licensed in California right
22 now.

23 I will be talking largely about 500
24 megawatt combined cycle plants of which one-third,
25 or perhaps 170 megawatts, is on steam. Now that

1 will make some of the numbers, in terms of
2 economic impact, come out lower than what you
3 heard this morning from our colleagues from Duke,
4 because they were talking about 1000 megawatts all
5 on steam. And it's just a different size.

6 If you carry around in your head a
7 number like 10 gallons per minute per megawatt --

8 PRESIDING MEMBER LAURIE: I don't
9 normally do that, but I suppose I could for a
10 brief period.

11 (Laughter.)

12 DR. MAULBETSCH: In some bizarre set of
13 circumstances it might even be useful.

14 PRESIDING MEMBER LAURIE: Yeah, nothing
15 else has worked, so I could try that one.

16 DR. MAULBETSCH: For the plant that I'm
17 talking about, for the steam side of a combined
18 cycle plant, that works out to about 3000 acrefeet
19 per year of water consumption for the condensation
20 of the steam coming out of the turbine.

21 There are other water loads at these
22 plants, but they're not very big. There's
23 auxiliary cooling; there's makeup to the steam
24 cycle; there's sometimes injection into the gas
25 turbines; and there's the so-called hotel load,

1 the air conditioning of the buildings and sanitary
2 water and so on, that in round numbers may be
3 something like 5 percent of that 3000 acrefeet.

4 MR. TOMASHEFSKY: What type of load
5 factor is that?

6 DR. MAULBETSCH: Beg your pardon?

7 MR. TOMASHEFSKY: What type of load
8 factor are you assuming with the 3000 acrefeet?
9 Is it running all the time?

10 DR. MAULBETSCH: I'd probably assumed
11 100 percent at that point, you know, if it's -- or
12 85 percent or something like that. These are all,
13 I mean you can see that's to one significant
14 figure.

15 MR. TOMASHEFSKY: Sorry.

16 DR. MAULBETSCH: So it's about 3000.
17 The usual method, and we're talking now about
18 these inland combined cycle plants, the usual
19 method of condensing the steam out of the turbine
20 is with a wet cooling tower.

21 Steam comes out of the turbine into a
22 shell and tube condenser. Cold water is run
23 through the tubes of the condenser; it heats up as
24 the steam condenses; and the hot water is then
25 returned to the top of a cooling tower where it's

1 spread out on a deck at the top.

2 And it sort of dribbles down through a
3 material called fill or packaging. And at the
4 same time a fan draws air from the surroundings
5 through that fill or packing. The air and the
6 water mix. A small portion, perhaps 1 to 2
7 percent of the water is evaporated.

8 The remainder is cooled by perhaps 20 or
9 25 degrees Fahrenheit and returned to the
10 condenser. That's typical recirculating wet
11 cooling.

12 PRESIDING MEMBER LAURIE: One to 2
13 percent, is that what results in the plume?

14 DR. MAULBETSCH: Yes, yes, under certain
15 circumstances. That evaporated water, as it leave
16 the tower, recondenses in the colder air and shows
17 you a visible plume on some days.

18 The operative environmental quantity
19 that tells you how much cooling you can get, how
20 cold you can get the water coming off that tower
21 is the so-called wet bulb temperature. Are you
22 familiar with that term, or --

23 PRESIDING MEMBER LAURIE: No, sir.

24 DR. MAULBETSCH: Okay, the normal
25 temperature or the dry bulb temperature is the

1 temperature that you measure with a regular
2 thermometer.

3 If you keep the bulb of that thermometer
4 wet, and air passes over it, some of that wetness
5 will evaporate and cool the bulb. That's why you
6 feel cold even on a warm day at the beach if
7 you're wearing a wet, sweaty t-shirt.

8 The wet bulb temperature is typically a
9 lot lower than the dry bulb temperature, and so
10 the water that you get off a wet cooling tower can
11 be a lot cooler than the water that you would get
12 off a dry cooling tower.

13 That's part of the reason, and we'll
14 talk about this more in a couple of minutes, that
15 the efficiency for dry cooling towers, as was
16 stated this morning, is less. You just can't get
17 as cold water off a dry tower as you can off a wet
18 tower.

19 This shows, if you're not familiar with
20 the equipment, a typical mechanical draft inline
21 cooling tower. You can see a little plume coming
22 off of the one on the left-hand side of the slide.
23 We talked about evaporation of about 10 gallons
24 per minute per megawatt, a blowdown, which my
25 colleague, Mike DiFilippo, will talk about more in

1 the next presentation, at some cycles of
2 concentration is perhaps 10 or 20 percent of that.

3 Drift, which is the small droplets that
4 sometimes get entrained in the air stream and
5 blown out the top of the tower is negligible from
6 a water consumption standpoint. It's still a few
7 gallons per minute, not per megawatt total. It's
8 a very small quantity of water.

9 There are other issues besides water
10 consumption with wet cooling. As was stated
11 several times this morning, the blowdown from the
12 tower, the water that you have to discharge from
13 the tower in order to limit the buildup of
14 suspended or dissolved solids that are brought
15 into the tower is an issue.

16 Drift deposition can be an issue if
17 there's salt in the drift or if it deposits on a
18 road in the winter and ices up. Plume visibility
19 can be an issue if it's in a place like over a
20 freeway where you want to be able to see. And
21 noise can be an issue, as was pointed out.

22 Now the same story for dry cooling.
23 Here, the steam when it comes off the condenser --
24 comes off the turbine, is taken out across the
25 property to an air-cooled condenser. The steam is

1 taken directly off of the tower.

2 It usually goes in on a steam header at
3 the top and is distributed. And as it condenses
4 it flows down those angled tubes which have fins
5 on the outside, and we'll see a picture of it
6 later, so you see what it looks like. Is
7 collected in condensate collectors at the bottom
8 of those tubes, and returned to the power plant
9 for revaporization, reboiling through the steam
10 condenser.

11 It's analogous, if you like, to an
12 automobile radiator where the stuff you're trying
13 to cool is inside tubes, it's being cooled by air
14 blown over the outside.

15 As we said a minute ago, what you get in
16 terms of cold water temperature off these is
17 determined by the normal or dry bulb temperature.

18 This is a picture of a dry cooling
19 tower. I think this is one of the same ones that
20 Detlev showed a couple of months ago. It's a
21 South African tower. You can see the sort of A-
22 frame construction; it's the structure to the left
23 of the buildings.

24 The water consumption for plants which
25 are dry cooled is not zero. You still have that 5

1 percent hotel and auxiliary load we talked about.
2 There's no blowdown, there's no drift, there's no
3 plume. Noise is still an issue, and in some cases
4 they may be noisier than a wet cooling tower
5 because you move a lot more air through a dry one
6 than through a wet one.

7 Okay, there's been a lot of talk about
8 the cost comparison between dry cooling and wet
9 cooling. There are a lot of ways to make that
10 comparison. What this plot in front of you shows
11 is just the capital cost ratio; this is just the
12 cost of the equipment.

13 For a wet tower it includes the tower
14 plus the condenser plus all the pumps and fans.
15 For a dry tower it includes the tower, the fans,
16 the motors, the steam ducting and so on.

17 It shows the results from about ten
18 different studies that have been conducted over
19 the years, some of them quite a few years ago.
20 And you see ratios that range from about 1, which
21 would suggest that the capital costs are equal, to
22 nearly 4.

23 I would say that for most situations the
24 answer is somewhere around 2, between say 1.5 and
25 2.5, if you compare an optimized wet cooling tower

1 designed to be the best wet cooling tower it can
2 be, with an optimized dry cooling tower.

3 PRESIDING MEMBER LAURIE: And how does
4 that translate into numbers of dollars? What kind
5 of dollars are we talking about?

6 DR. MAULBETSCH: Okay, well, let's look
7 at the next slide. These are costs for a dry
8 cooling tower. And it's in dollars per kilowatt.
9 So for 170 megawatt steam side of the plant that
10 we were talking about, you have to multiply those
11 numbers by 170,000.

12 So where it says \$100 per kilowatt,
13 that's a \$17 million tower. It's plotted against
14 what they call the initial temperature difference.
15 That's the temperature that you're condensing the
16 steam at minus whatever the temperature of the air
17 outside is at the time.

18 So, when that number is big, over on the
19 right-hand side, at 50 or 60 degrees Fahrenheit,
20 you can get away, for a fixed load, with a
21 relatively small tower.

22 If you want the tower to meet design
23 conditions on much hotter days, down where there
24 might be only 20 or 30 degrees different, then you
25 have to have a much bigger tower which costs

1 correspondingly more.

2 So the cost, depending on how you select
3 the design point, can vary by, on this plot, a
4 factor of 2.5.

5 The costs of dry cooling with changes in
6 atmospheric conditions are more variable than wet
7 cooling, because the wet cooling, you could
8 construct a similar plot here for wet cooling, I
9 haven't done that, but you could.

10 But you would plot it against what they
11 call the approach temperature, which is the hot
12 water temperature of the cold water temperature
13 leaving the tower, subtract it from the
14 atmospheric wet bulb temperature.

15 Wet bulb temperature varies a lot less
16 from cold days in the winter to hot days in the
17 summer than dry bulb temperature does. And so the
18 variation is somewhat less.

19 However, if you go back to the previous
20 slide, and we don't need to do that necessarily,
21 but if I said that there was typically between
22 optimized dry and optimized wet, perhaps a
23 difference of a factor of two.

24 So for this 170 megawatt steam side
25 power plant, let's take the point and say 30

1 degrees, and so we're at about \$200 per kilowatt,
2 that's a \$34 million tower. Half of that is \$17
3 million. So the difference between the two in
4 capital costs might be \$15 to \$20 million.

5 Why do dry cooling towers cost more?

6 Well, there are a number of reasons for that. If
7 you look at the next slide, this is a tube that
8 you would find in a dry cooling tower. It's more
9 expensive to make metal tubes with extended
10 surfaces on the outside than it is to make splash
11 packing that water dribbles down over in a dry
12 cooling tower.

13 So the surface, itself, where the heat
14 transfer takes place, is more costly. In a wet
15 tower you also have to pay for a condenser, but
16 even the combination is more costly for dry.

17 You have to move a lot more air to cool
18 dry than you do wet. So, more fans and more
19 motors are required, and that's a significant
20 portion of the cost of the tower.

21 And the configuration we talked about,
22 you have to bring the steam from the turbine hall
23 out to where the tower is. Steam at that pressure
24 is not very dense, and so you have to move a lot
25 of volume of steam. So these tubes are very

1 large. And you can see those two white lines
2 going along the top of the dry cooling tower
3 represent the steam ducting, and that's a
4 significant cost to purchase and to support.

5 Okay, now let's assume we have chosen a
6 dry cooling tower and we've asked that it meet
7 turbine design conditions at say a 65 degree
8 ambient day, or a 75 degree ambient day.

9 And then the summer comes along and it
10 gets hotter out there. As the temperature goes up
11 for three different turbines that I've selected
12 here from 65 or 75 up to 100 or higher, the so-
13 called back pressure on the turbines, the pressure
14 at the back of the steam turbine that the steam is
15 exhausting out to, goes from 2.5 or 3.5 inches of
16 mercury, which is a pretty high vacuum, up to 6 or
17 8 or 10 inches of mercury.

18 When that happens the turbine performs
19 less efficiently. And on the next plot you see a
20 plot of turbine back pressure which we just said
21 goes from 2.5 or 3.5 at design up to 6, 8 or 10.
22 When that happens the efficiency goes down and
23 heat rate ratio -- heat rate is defined as the
24 amount of energy that you have to put into the
25 plant, divided by the amount of energy you get out

1 of it as electricity.

2 And this has been normalized to the
3 design point, so at 1 that's the plant operating
4 at normal design conditions and a back pressure of
5 say 2.5. Gets hot out, temperature goes up, the
6 back pressure goes up to 8 or 10. The heat rate
7 ratio is 1.1.

8 Well, that corresponds pretty closely to
9 what Wayne Hoffman said this morning about a 10
10 percent reduction in output, of going from -- he
11 was talking about once-through cooling versus dry
12 cooling, but the dry cooling tower goes up there,
13 it's about -- I have no quarrel with his estimate
14 of perhaps a 10 percent reduction.

15 How much is that penalty worth? Well,
16 here we get into stuff that I guess is something
17 you deal with a whole lot more than I do. If you
18 lose 10 megawatts, let's say, from the output of
19 the turbine, which would be, say, a 5 or 6 percent
20 reduction in output on this 170 megawatt steam
21 section that we're talking about, and that lasts
22 for a few hundred hours a year when the
23 temperature outside is hot enough so that you
24 suffer that kind of a loss.

25 How much it costs you depends on how

1 much power is worth. I don't know how much power
2 is worth. I don't even know how much it costs
3 anymore.

4 (Laughter.)

5 DR. MAULBETSCH: But I picked some
6 numbers ranging from \$55 a megawatt hour which is
7 one that we read in the paper a lot, up to \$250 a
8 megawatt hour. And so if this 10 megawatt loss
9 lasts for say 400 hours, that can cost you, on
10 this 170 megawatt plant, somewhere between a few
11 hundred thousand and a million dollars.

12 If power's worth \$750 a megawatt hour,
13 you know, you can do the arithmetic as well as I.
14 It can get very costly, as was pointed out.

15 Now, what could you do about that? One
16 thing you can do, I think this was also mentioned
17 by someone this morning, if you have a little bit
18 of water available you can use a little bit of
19 water at the time of the year when the hot weather
20 is really hurting you. And then go dry during the
21 rest of the year. And you may use water at a
22 pretty high rate during the times that you need
23 it, but averaged over the year you use
24 substantially less.

25 There are so-called hybrid wet/dry

1 systems. You were asking about the plume before.
2 Most of the ones that are out there around the
3 country and around the world are not so much for
4 water conservation as they are for plume
5 abatement.

6 If you have a plume on a cold day and
7 you don't want it, you can heat the plume up a
8 little bit and you can heat the discharge air
9 coming off the wet tower a little bit and the
10 plume will go away.

11 Another thing you can do, and this is
12 taking a book from the gas turbine people, gas
13 turbines also suffer a capacity reduction on hot
14 days, because they suck in a certain volume of
15 air. And as the air heats up, that means you get
16 less massive air for the same volume. So the
17 capacity of the turbine goes down.

18 What they do is to spray finely atomized
19 water in the gas turbine inlet. That water
20 evaporates, cools the air, and it recovers some of
21 the megawatts for you. One could consider doing
22 the same thing for a dry cooling tower. But the
23 remaining slides, which we can go through very
24 quickly, just show some of the alternatives for
25 these hybrid systems.

1 The first one is a single tower design
2 where you have essentially a wet tower on the
3 bottom, a dry tower on the top and louvers to
4 direct the air to whichever one you want or to
5 some fraction of the air to whichever one you
6 want.

7 This is the usual plume abatement
8 design, because the size wet tower that you can
9 put on top -- I'm sorry, the size dry tower that
10 you can put on top of a wet tower is pretty small
11 compared to the size dry tower you would need to
12 carry the whole condensing load.

13 PRESIDING MEMBER LAURIE: And these are
14 available now?

15 DR. MAULBETSCH: These are available
16 now, yes. From at least one supplier, and perhaps
17 it -- at least two suppliers and perhaps three.

18 The next is a split steam design where
19 you essentially have two parallel cooling systems,
20 a wet cooling tower on one side of the plant, with
21 its condenser, and a dry cooling tower on the
22 other side of the plant.

23 And you have a steam duct that takes
24 some of the steam to the condenser and some of the
25 steam to the dry cooling tower.

1 Well, that will work, but if you build
2 both of them full size, you're dealing with a
3 substantially increased capital cost. You have to
4 pay the full price for both towers. That's not a
5 system that I am aware is in place anywhere, at
6 least at full size.

7 PRESIDING MEMBER LAURIE: To your
8 knowledge when you talk about hybrid system
9 availability, are the systems readily available on
10 the market? Is there a delay?

11 And if, for example, a developer doesn't
12 know until a project is certified what kind of
13 cooling system they require, and therefore cannot
14 place an order until day 365, do you have any idea
15 about --

16 DR. MAULBETSCH: I don't know the answer
17 to that, sir. I don't think the cooling tower
18 vendors are terribly backed up right now. But I
19 don't know that to be true. I can find out and
20 I'll let Joe and Matt know, and they can pass the
21 information back to you.

22 PRESIDING MEMBER LAURIE: Does Duke
23 know? Do you guys know?

24 MR. HOFFMAN: Wayne Hoffman with Duke
25 Energy. I'm not sure what the lead time is on

1 these, except that on the dry cooling systems
2 there tends to be a considerably longer lead time,
3 as this gentleman, I'm sure, would agree, because
4 of the more complicated design nature.

5 Generally, a cooling tower system is
6 pretty low tech, often made out of treated lumber
7 in large part. So, those can be designed and
8 built readily.

9 I would point out, though, that
10 combining these two systems can be extremely
11 costly. And is not being looked at by developers
12 for that reason.

13 PRESIDING MEMBER LAURIE: Okay, thank
14 you, Wayne.

15 DR. MAULBETSCH: A third option is I
16 guess what's often called a swamp cooler, where
17 you simply precool the air going in with something
18 that looks like a conventional wet tower. But
19 that water that's going around in the wet tower is
20 just recirculated from bottom up to the top. And
21 serves really only to cool the inlet air, not the
22 condensed steam directly.

23 The next slide, this is an example of
24 the inlet gas turbine cooling racks that I was
25 talking about. And what they do in front of the

1 air intake is just put up racks with a bunch of
2 little nozzles; spray high pressure water through
3 the nozzles; make a mist and it cools the air.

4 As I say, you could consider doing that
5 in dry cooling systems. And I think it's a system
6 that deserves being looked at. A lot more air
7 goes through a wet cooling tower -- or goes
8 through a dry cooling tower than through a gas
9 turbine.

10 And so you would have different design
11 parameters to deal with. But the thermodynamics
12 is straightforward. If you evaporate water in the
13 inlet air you'll cool it down and that will help.

14 There was a study of this done by a
15 student of Kroeger's a couple years ago, and this
16 doesn't refer to any particular plant, this is
17 just arithmetic basically. But, it shows here,
18 for example, that for a 235 megawatt unit, which
19 they chose as their basecase to look at, as the
20 temperature rose from about the mid 50s up to 90
21 or above, it represented a 10 or 12 megawatt
22 decrease in capacity.

23 If you precooled the air to 70 percent
24 relative humidity, which I think amounted to about
25 a 10 or 15 degree reduction in temperature, you

1 recovered most of that loss in capacity. Instead
2 of losing 10 to 12 megawatts, you lost 3 to 5
3 megawatts.

4 And the rate at which you were using
5 water during the period you were using it was
6 about one-quarter of the rate that you would use
7 the water if you were cooling the whole thing with
8 a wet cooling tower.

9 And the capital cost increase for this
10 kind of a precooling spray arrangement is
11 certainly minimal compared to the hybrid tower or
12 the split steam section, which, as Wayne pointed
13 out, can be quite costly.

14 So, finally, I guess I would leave you
15 with one which you already knew, that water saving
16 cooling technologies exist. Their costs are
17 higher than conventional wet cooling technology,
18 except in maybe some very special circumstances.
19 Capital costs are higher and the plant output is
20 reduced due to some operating penalties of lost
21 capacity or efficiency.

22 But adding a small amount of water to
23 dry cooling systems can reduce those
24 inefficiencies. It can be done in a way, I think,
25 that does not increase the capital cost

1 tremendously above what you already have to pay
2 for dry cooling.

3 And so you can help yourself by using a
4 little bit of water, as opposed to trying to use
5 none at all.

6 PRESIDING MEMBER LAURIE: But the lesson
7 learned and the fact is that when you get into
8 southern California, the further off the coast you
9 get the hotter it is, and less water availability
10 you have.

11 That's not fair.

12 (Laughter.)

13 PRESIDING MEMBER LAURIE: Because it's
14 inconsistent with what our need is. And it's
15 inconsistent with the inefficiencies of the needed
16 technology that is currently available. So the
17 question is what is your awareness of current
18 research being done to increase the efficiencies
19 of dry cooling?

20 DR. MAULBETSCH: There is work being
21 done on the heat exchanger surfaces; that tube
22 that I showed you a few slides back, which was a
23 round tube with round fins on it. They are
24 getting more effective towers at lower costs by
25 using tubes that aren't round, but are long and

1 almost rectangular with rounded ends and special
2 fins mounted on those.

3 It was always recognized that those
4 would give you less fan power for more effective
5 heating, but round tubes are easy to make and
6 these aren't. And so they've been working on the
7 manufacturing techniques. And that seems to be
8 working.

9 MR. O'HAGAN: I just wanted to point out
10 that staff is proposing a tailored collaborative
11 with Mr. Maulbetsch through EPRI under the PIER
12 program to evaluate the spray enhancement for dry
13 cooling facilities. You'll probably be seeing
14 that in a different capacity.

15 PRESIDING MEMBER LAURIE: I anticipate
16 so. Thank you, sir.

17 MR. O'HAGAN: Our next speaker is
18 Michael D. Filippo, and he's going to be talking
19 about degraded water use for power plant cooling.

20 MR. DiFILIPPO: I want to show you some
21 overheads. Now, you should have a copy of this up
22 there. I pulled some of the overheads out. You
23 don't?

24 Some of the overheads I'm going to show,
25 some of the material that's in the handout is not

1 in the overheads, because I pulled them out.
2 They're kind of simplistic. I'm just going to
3 jump over those.

4 Like Joe said, I'm here to talk about
5 degraded water for power plant cooling. And why
6 don't we just go to the next overhead.

7 This is the cooling tower that John
8 talked about. Basically water, regardless if it's
9 fresh water or degraded water, enters the cooling
10 tower and it's used for cooling.

11 You get a significant amount of
12 evaporation. I deal in gallons per minute. You
13 get about 1700 gallons a minute of evaporation for
14 this size power plant, about a third of it using
15 steam power and cooling for condensing steam.

16 A cooling tower is designed so you
17 maintain a constant volume of cooling water, and
18 that's done with -- you have water evaporating;
19 you have dry air, relatively dry air going into
20 the tower. It humidifies basically with cooling
21 water, some of the water evaporates, pulls a lot
22 of heat out, about 1000 Btus per pound of water
23 evaporated. That's your cooling, your heat
24 rejection.

25 Now, to compensate for that -- makeup

1 for that volume loss, you add what is known as a
2 makeup stream, which is your fresh water or
3 degraded water, whatever water source you have.

4 As the water's evaporating it's
5 concentrating at the same time. And if you didn't
6 bleed that salt out, in other words you've got so
7 much fresh water coming in that contains natural
8 background salts. If you did not bleed those
9 salts out they'd stay in the tower, because they
10 don't leave in the evaporation, and the
11 concentration of salts would increase very
12 dramatically.

13 So, there's a bleed stream called
14 blowdown. And this is a practical stream. It's
15 used to control salt concentrations in the tower.
16 And this stream generates water quality, water
17 concentrations and a ratio known as cycles of
18 concentration.

19 And if we can flip to the next one,
20 which is about two pages back for you guys, it's
21 another cooling tower. It shows flow rates here.
22 Now, what this tower's showing is 10 cycles of
23 concentration. And what that means is that we've
24 pulled enough of a bleedstream off to get ten
25 cycles of concentration in the cooling tower.

1 Now, cycles of concentration, the higher
2 the cycles of concentration the less the blowdown
3 you have, the less salt you're taking out of the
4 tower. The less salt you have to take out of the
5 tower, the smaller the blowdown stream, the
6 smaller the wastewater stream you have to contend
7 with, especially for an inland plant.

8 Inland plants, and it was said this
9 morning, try to achieve as high cycles of
10 concentration as possible. Now, with fresh water,
11 especially in some areas fresh water can allow you
12 to go up to 15, 20 cycles of concentration.

13 Degraded water, and I've showed Joe many
14 examples of degraded water where you're lucky if
15 you can get five cycles, six cycles, seven cycles
16 of concentration.

17 Let's go to the next overhead, next
18 page. These are just graphical relationships. As
19 you can see, when you get to five cycles of
20 concentration, four and a half to five cycles of
21 concentration, the makeup demand for water kind of
22 starts to level off. That's the top graph.

23 When you go down -- the graph below just
24 shows you just the blowdown stream component. The
25 red line of the top graph is blowdown. The top

1 line is makeup.

2 So a lot of coastal plants that have
3 cooling towers operate at 4.5 to 5 cycles of
4 concentration. Number one, they can discharge
5 their water usually to a receiving body. And
6 number two, the cycles of concentration are lower,
7 the water quality -- the concentrations of salts
8 in the water that create corrosion, that create
9 what is known as hardness, scaling, which covers
10 heat transfer surfaces, reduces the efficiency of
11 the overall power cycle, those are reduced when
12 you can operate at lower cycles of concentration,
13 lower salt concentrations.

14 So in coastal plants you'll typically
15 see five cycles of concentration, maybe seven or
16 eight. And there's no need to go higher, because
17 you have a receiving body of water.

18 In the inland plants you have to go as
19 high as you can because every gallon water,
20 especially in -- most inland plants are zero
21 discharge plants. They either have to go to an
22 evaporation pond, a receiving body that will take
23 this water and keep it away from groundwater. Or
24 put in some fairly sophisticated equipment to
25 evaporate either to reduce the volume

1 significantly or to just take it away completely.

2 But let's go to the next slide I'll show
3 you. Now, before I go any further with equipment,
4 let's just look at some degraded water sources.

5 I've just completed some work in this
6 area for the Commission and there are a whole
7 series of degraded water sources in California.
8 There's contaminated groundwater, and that's just
9 groundwater that's contaminated by something. It
10 could be solvents, it could be heavy metals. It's
11 typically drinking water supplies that are
12 impacted.

13 There are brackish surface waters and
14 brackish groundwaters. The central valley has got
15 a significant number of salt sinks where you have
16 brackish groundwater.

17 You have agricultural water which is in
18 some areas a fairly significant volume of water.
19 It's somewhat seasonable, but fairly significant
20 volume of water.

21 And then in the coastal areas you've got
22 reclaimed municipal effluent in large quantities.

23 PRESIDING MEMBER LAURIE: Do we care
24 what's in the water? And, if so, why? Is it
25 because of the evaporative portion of it?

1 MR. DiFILIPPO: Yeah, that's the next
2 page. Why don't we turn to the next page.

3 The first one, common minerals. This is
4 what's typically in all waters. Tap water's got
5 common minerals. It's just hardness and
6 alkalinity and sulfate and silica and chlorides.
7 These are natural background minerals.

8 Reclaimed water, in addition to that,
9 which it's usually a little more salty. It has
10 BOD, COD, these are organic compounds. Very low
11 levels. THM precursors. Now, these are chemicals
12 that are generated in the cooling tower when you
13 chlorinate the water for disinfection, you get
14 CHMs. They're known as -- they're precursors to,
15 they are carcinogenic compounds. They're very
16 hard to control.

17 There's also ammonia and phosphate. And
18 those two compounds, alone, create big problems
19 with cooling systems. And I'll get into that in a
20 second.

21 You also get hazardous contaminants,
22 depending on the water you could have heavy
23 metals, volatile organic compounds or VOCs, non-
24 VOCs but they're still organic compounds. You
25 could have pesticides.

1 And then there's other chemical
2 constituents. For chlorate -- MTBE is not up
3 there, but that's obviously another one. You
4 could have nitrates which at very high levels can
5 create problems with pregnant women, for instance.
6 And then there's sulfides and fluorides.

7 So, there's a whole variety of things
8 that can be in contaminated water or degraded
9 water. And these are just various components of
10 it.

11 Now, if we can turn to the next one, you
12 know what I want to do, let's go to the one after
13 that and then I'll come back to that one.

14 Okay. When you've got degraded water,
15 you know, there's different things you can do with
16 it to use it for cooling towers. You just can't
17 put the water in the cooling tower without
18 treating it.

19 And depending on what the contaminants
20 are, you're going to have to treat it, in some
21 cases for contaminated groundwater before you can
22 put groundwater that has volatile organic
23 compounds in it, into a cooling tower which will
24 strip them right out. You've got to pretreat to
25 get those materials out of the tower.

1 There's some general minerals that you
2 have to remove from the water before you put them
3 in the tower, depending on what their
4 concentrations are. And that's --

5 PRESIDING MEMBER LAURIE: Can you do
6 that all on site?

7 MR. DiFILIPPO: Oh, yeah. And
8 interestingly enough, these technologies are all
9 commercial available technologies. There's not a
10 lot of R&D stuff here, relatively speaking.
11 They're all commercially available technologies.
12 Softening, adjusting pH, reducing silica, removing
13 total dissolved solids, which is TDS, these are
14 all commercially available technologies. They
15 just cost money and they use chemicals, and in
16 some cases, power.

17 In some cases the water has so many
18 constituents in it of concern, when I say concern,
19 that are of concern to the cooling tower, that you
20 have to actually use -- you utilize side stream
21 softening, which basically takes a portion of the
22 hot water coming back from the condenser, and you
23 soften that, or you treat it somehow and return
24 that to the tower.

25 In inland plants you may have to go all

1 the way to post-treatment, and that's where you
2 basically take the blowdown from the cooling tower
3 and reduce its volume so you can put it in a small
4 evaporation pond. Or reduce it to dryness, that's
5 another alternative for cooling towers. And there
6 are some power projects that are utilizing this
7 technology, which has been around since the early
8 '70s, evaporation for these purposes. Used in
9 power plants since the early '70s.

10 A lot of zero discharge plants built in
11 1975, 1978, utilize this type of technology today.

12 Let's go back to the one I skipped over.
13 Now, every time, generally speaking, when you
14 increase the cycles of concentration, in other
15 words try to reduce the volume of wastewater,
16 things happen.

17 When you increase the cycles of
18 concentration the salt concentration in the
19 cooling tower increases dramatically. So you have
20 the condenser that where all the condensation
21 happens for the steam turbine, the metallurgy may
22 have to go from what is a brass metallurgy to a
23 copper/nickel metallurgy.

24 And if you really want to increase the
25 concentrations even further, you may have to go to

1 titanium. And these all cost more money,
2 significantly more money to build.

3 When you increase the cycles of
4 concentration your costs go up, your chemical
5 costs. There are specialty chemicals that are
6 added to the tower to help prevent scale
7 formation, biological formation, sedimentation
8 happening in low flow areas.

9 So these are all costs that are involved
10 with increasing cycles of concentration. And
11 interestingly enough, whether it's fresh water or
12 degraded water, the higher the cycles of
13 concentration the more chemicals you'll spend.

14 Degraded water you'll spend more because
15 it's harder to get the higher cycles of
16 concentration anyway. You probably have to treat
17 for that.

18 Let's go, I guess we're going to have to
19 skip two, get to the next one. There we go. Now,
20 this one here, what this one shows is the same
21 levels of treatment, pretreatment, side stream
22 treatment, post treatment.

23 Now, with inland plants you've got to go
24 all the way to post treatment, because what are
25 you going to do with all this blowdown? Okay,

1 you're going to try and get the cycles as high as
2 you can and you're going to have to do post
3 treatment, which typically is volume reduction and
4 storage on site of the reduced volume of water, or
5 basically salt.

6 Alternatively, with coastal plants you
7 may have to do pretreatment, you may have to do
8 side stream treatment, depending on the water and
9 its quality and the constituency, the chemicals
10 that are found in the water.

11 So, there's a big difference between the
12 two. And inland plants are really distinguished
13 because they have this waste stream they have to
14 handle, in some cases, dryness.

15 Let's go to the next one here. Okay. I
16 want to talk about post treatment disposal
17 options. There really are three kinds -- there's
18 three levels of treatment.

19 There are plants out there in the desert
20 that just have evaporation ponds. They're huge,
21 150 acres, 200 acres of ponds. I personally
22 designed two plants that had huge evaporation
23 ponds. They don't build them like that much
24 anymore. These were all built in the '70s.

25 You can reduce the volume of waste with

1 what is known as a brine concentrator or an
2 evaporator. And what it does is it uses an
3 evaporation technology to evaporate the water down
4 to about 10 percent of its original volume.

5 So if you start with 100 gallons a
6 minute, you end up with ten gallons a minute of
7 waste stuff. And this stuff is pretty yucky
8 looking. A lot of salts in it. It's very thick
9 and heavy.

10 And then you get this water that the
11 distillate is high quality water that can go back
12 to the plant. You can actually take a credit for
13 it, because it's high quality water.

14 The waste, if you just had a brine
15 concentrator, you'd have to go to a smaller
16 evaporation pond. And just store it in there.

17 And then the last, of course, is a brine
18 concentrator with a crystallizer. And what a
19 crystallizer does is it takes that reduced volume
20 of waste and brings it to dryness. And these
21 crystallizers are becoming more popular now.

22 I was involved in a crystallizer design
23 in 1980. It was huge. It was an electric one.
24 And we spent -- it was a very inefficient system.
25 The ones today are more efficient. And I've got

1 some slides I'll show you of how these combined to
2 get -- as a matter of fact, why don't we go to the
3 next one.

4 This is just an evaporation pond. Now,
5 in the central valley you'll get about for every
6 gallon a minute of wastewater you have, you need
7 about a half an acre of an evaporation pond in the
8 central valley.

9 In the desert you only --

10 PRESIDING MEMBER LAURIE: I'm sorry,
11 give me that number again.

12 MR. DiFILIPPO: For every gallon per
13 minute of wastewater you need half an acre of
14 pond. In the high desert, like in Blythe, for
15 instance, a third of an acre is kind of the rough
16 number.

17 So, these evaporation ponds can be
18 significantly big. Now, the other thing about
19 evaporation ponds are they're storing salt is what
20 they're doing. They're huge. And in the
21 summertime they look like they're way oversized
22 because they look like you got a lot of dry
23 surface.

24 In the wintertime the water's rising.
25 So you have to size them so you can take all the

1 cycles. The wet years, the dry years. It's a
2 fairly complex analysis to size these things.

3 And in the meantime you get a fairly
4 large load of salt, 30 years of salt accumulate in
5 these ponds. Sometimes the ponds have to be dug
6 out, taken out of service and dug out. So they're
7 not as simple as they look.

8 And for that reason a lot of people
9 don't like to build something this big. And you
10 also have to have the acreage to do it. And they
11 only make sense in very dry climates. This would
12 be crazy on the coast, because there's not enough
13 land, and it has to be flat. That's the other
14 rule for evaporation ponds. As soon as you start
15 getting a wavy surface the costs go out of sight,
16 and they don't make any sense.

17 Okay, let's go to the next one. Now,
18 this is the brine concentration I told you about.
19 Now, interestingly enough, you can reduce the
20 waste fairly significantly. What it does is it
21 takes you to one-tenth of what you would have had
22 if you didn't have a brine concentrator.

23 But it takes about a megawatt of power
24 to drive it. And that's power off -- that's power
25 before you sell it. That's power off the grid

1 before it's sold.

2 You do generate a very high quality
3 stream of water which can be used for boiler
4 makeup, a little extra treatment for boiler
5 makeup, gas turbine injection for NOx control.
6 Those are some typical uses for that water.

7 And then the next one shows, if we just
8 want to get rid of the evaporation pond
9 completely, you go to a crystallizer. And you end
10 up with a pile of salt at the end of the day.

11 And from what I've seen salt is
12 generally it's a nonissue. It's just salt. A lot
13 of people just leave it on site; some people pay
14 somebody to take it away and dispose of it, you
15 know, legally, by disposing it to a disposal
16 site. So, those are the issues.

17 Now on the next page I can just show you
18 some ideas of what these numbers look like. The
19 option one is just an evaporation ponds. You're
20 looking at for a 500 megawatt plant, ten cycles of
21 concentration, and that may require some treatment
22 to get there because the water's highly degraded.
23 You're looking at 94 acres of ponds in the central
24 valley versus 63 acres in the desert.

25 And then you can see that the ponds get

1 dramatically smaller as you put an evaporator in.
2 And then if you have a crystallizer, you have no
3 ponds. And then you have a power requirement
4 also, almost a megawatt for an evaporator for this
5 plant. And 1.2 megawatts for an evaporator
6 crystallizer.

7 MS. TOWNSEND-SMITH: Are there many
8 plants using a crystallizer?

9 MR. DiFILIPPO: Yeah, there's probably
10 four or five out there right now, all over the
11 place. There's one -- there's how many, Joe, in
12 California? Two? One?

13 MR. O'HAGAN: Well, the High Desert is
14 certified. It has a crystallizer. Sutter is
15 going to use a crystallizer for the cooling tower
16 blowdown clearly, but the steam cycle blowdown,
17 HRSG blowdown. LaPaloma has a crystallizer.

18 LaPaloma has a crystallizer. Sutter has
19 a crystallizer for the HRSG blowdown. And
20 LaPaloma has a crystallizer.

21 MS. TOWNSEND-SMITH: Well, any in
22 operation? I mean, I know they were all --

23 MR. O'HAGAN: Not that I'm aware of in
24 California. Elsewhere, though, I know Calpine has
25 a couple units up in the Pacific Northwest that

1 use crystallizers. And back east there's quite a
2 few.

3 MR. DiFILIPPO: The use in other --

4 MS. TOWNSEND-SMITH: Okay, because I
5 remember --

6 MR. DiFILIPPO: They're used in other
7 industries extensively to recover ore, for
8 instance. You'll have a solution of ore and
9 water, and they actually use them in other
10 applications, as well.

11 They've been around for years and years
12 and years. This is sort of a new application for
13 this technology. But Joe's right, it's an old
14 technology, it's been around for a very long time.
15 And, you know, I don't think there's a lot of risk
16 involved in specifying one for a plant because
17 they should work.

18 And then on the last page I just tried
19 to put some costs together based on -- I got some
20 costs for evaporators and crystallizers for one of
21 the major suppliers of this equipment. And
22 they're very reputable.

23 And you can see there's a dramatic
24 difference in the cost. If you just went with
25 straight evaporation ponds, you know, they cost

1 about, my estimate was about \$350,000 an acre.
2 And that's flat land, and that's a pond that won't
3 leak. It has to be certifiable, won't leak. It
4 has to be engineered. It's lined. It has sensing
5 devices below the surface, below the bottom of the
6 pond to detect any kind of leakage.

7 So it's a fairly significant expense.
8 And you can see that it does make sense to go with
9 evaporation technology especially in the central
10 valley, crystallizing technology, because it's
11 even a little cheaper, because you don't have as
12 good evaporation there.

13 In the desert, because the evaporation
14 rate is so high, it's almost a wash. It doesn't
15 make -- to me it doesn't make sense to put a
16 crystallizer in when you can put a tiny little
17 evaporation pond in.

18 That concludes my --

19 PRESIDING MEMBER LAURIE: Question.
20 When you go back to your note regarding the
21 available types or sources of recycled water, and
22 then you look at those areas of California that
23 are more likely to have fresh water shortages.
24 And you look at the sources of the alternatives.

25 Do they match? That is, in those

1 geographical areas where there may, in fact, be
2 greater pressure on water services, are you just
3 as likely to find alternative recycled sources as
4 anywhere else? Or is that too difficult to
5 determine?

6 MR. DiFILIPPO: Well, I know for the
7 central valley there are a lot of salt sinks. And
8 some are not that degraded, the waters. Maybe
9 they have a couple thousand TDS of salt content,
10 but they're useable. They're sort of like slight
11 brackish water.

12 So the central valley has got some
13 opportunities for this kind of water use.

14 The high desert, I'm not sure. I've
15 done a couple of designs in the desert. And we
16 used adjudicated water rights. I mean we actually
17 owned the rights to the water, so we just used the
18 water rights we had for that.

19 But I can't answer for the high desert.

20 PRESIDING MEMBER LAURIE: Okay.

21 Gentlemen, thank you very much.

22 What I'd like to do is hold off on
23 questions for a bit, because I, I'm sure like a
24 lot of you, have to get to the airport and I don't
25 want to rush our next presenters.

1 So, if we can hold our questions for
2 awhile. Are you gentlemen going to be here for a
3 few minutes, anyway? Okay. Thank you very much.

4 MR. O'HAGAN: Thank you, Commissioner
5 Laurie. The next panel, panel 3, is dealing with
6 water policy. And I think that hopefully this
7 morning's presentations and the presentation by
8 Mike and John raise some serious policy question
9 issues that we know that speaking of dry cooling,
10 certainly technologically is feasible, does
11 present certain costs and efficiency losses, maybe
12 even some system reliability or capacity concerns.

13 Also using degraded water, you know, if
14 things aren't available is it ever appropriate to
15 use potable water, or potable quality water. And
16 hopefully that these things will be touched upon,
17 or certainly discussed later today.

18 The three speakers we have lined up for
19 the water policy discussion are Gerald Meral,
20 Michael Jackson and Kaitilin Gaffney.

21 PRESIDING MEMBER LAURIE: Thank you very
22 much.

23 MR. BUELL: I believe Jerry Meral is not
24 here yet, but we can proceed with these speakers.

25 PRESIDING MEMBER LAURIE: Okay. Good

1 afternoon, folks. Thank you for joining us.

2 MR. JACKSON: My name is Michael
3 Jackson; I'm a water attorney. And I represent
4 the Regional Council of Rural Counties, which is
5 28 northern California counties or Sierra
6 counties, both on the central valley floor and in
7 the mountains above.

8 PRESIDING MEMBER LAURIE: Know them
9 well, just had a meeting with your energy folks
10 the other day.

11 MR. JACKSON: Well, thank you very much.
12 We appreciate it, that's where we've been.

13 Basically our view is that there is
14 ample water for the siting of these plants above
15 the delta diversion facility. That would mean the
16 mountains, the foothills, the Sacramento Valley,
17 but not probably in the delta, itself, or in the
18 San Joaquin Valley.

19 The reason is that the water system is
20 not sized or located in a way that water can be
21 distributed equally about the state. And the
22 problems are getting worse, not better.

23 And consequently, we feel that potable
24 water should not be used in a situation in which
25 there are other alternatives.

1 And that as I listen to the testimony in
2 regard to evaporation ponds, salt is the major
3 problem in water in California. And the use of
4 evaporation ponds, either at the Kesterson
5 facility or at other facilities in the San Joaquin
6 Valley has made it very clear that not only is the
7 groundwater something that can be polluted by
8 evaporation ponds, and has been, but there is a
9 tremendous problem with the Pacific flyway even if
10 the evaporation pond does not leak.

11 The Kesterson experience has been one
12 that has been repeated all over the west in places
13 where evaporation ponds have been used, and
14 basically unless you can protect avian species,
15 the flyway, itself, evaporation ponds are destined
16 to fail.

17 Consequently I was very glad to see the
18 information about crystallizers, about dry
19 methodologies. It seems that in terms of a long-
20 term future, it would be appropriate to use only
21 presently polluted sources for water supply
22 generally depending on the amount of treatment you
23 would use, the TDS number that folks are trying to
24 reach is below 500.

25 So, basically any waters over that

1 amount would be appropriately use, I think, for
2 this kind of use for the state.

3 But the evaporation pond technology in
4 the San Joaquin seems to me to be something that
5 you would not only have a source supply, but a
6 disposal supply. And an existing condition that
7 the water system has never been able to deal with.

8 And consequently expanding it now to
9 both energy and water in the San Joaquin Valley
10 would be a great step backward in our opinion.

11 PRESIDING MEMBER LAURIE: Joe, do you
12 know which applications we have, if any, for the
13 San Joaquin?

14 MR. O'HAGAN: That have evaporation
15 ponds?

16 PRESIDING MEMBER LAURIE: For
17 applications for power plants. Do we have any
18 that are located in the San Joaquin Valley?

19 MR. O'HAGAN: Yes. We just certified
20 Elk Hills Power Project. There's the Midway-
21 Sunset facility. Those are on --

22 PRESIDING MEMBER LAURIE: Yeah, but
23 that's down south, right?

24 MR. O'HAGAN: Right, San Joaquin.

25 PRESIDING MEMBER LAURIE: Is that still

1 considered -- how far south does San Joaquin
2 Valley go?

3 MR. O'HAGAN: Tehachapi.

4 MR. JACKSON: The San Joaquin Valley
5 actually technically, in terms of the hydrology,
6 only goes to Fresno. But the Tulare Basin has the
7 same problems with salts building up to the level
8 now that many of the growers are beginning to lose
9 ability to grow crops because of the buildup of
10 salts now.

11 And to add to that, if there is another
12 place to site these facilities, -- I mean I'm sure
13 there are micro-sites that would be able to
14 operate on groundwater that was not potable or not
15 usable for agriculture.

16 But in general, I think that's something
17 that ought to be looked at very closely because
18 this water is, as power, becoming more and more
19 expensive. And transferring its use from the
20 environment and agriculture in an area that is
21 that critical to both the economy and the
22 environment would seem to me to be something that
23 ought to be addressed carefully in terms of
24 siting.

25 PRESIDING MEMBER LAURIE: One issue, and

1 this is speculation on my part because I haven't
2 had a chance to chat with you about energy water
3 policy in the rural counties. But in the rural
4 counties water is always an issue. It's in the
5 rural counties that often claims source of origin.

6 MR. JACKSON: Yes.

7 PRESIDING MEMBER LAURIE: Is that the
8 right terminology?

9 MR. JACKSON: I spend most of my day
10 talking about that.

11 PRESIDING MEMBER LAURIE: Well, I've
12 been in El Dorado for 28 years, so I --

13 MR. JACKSON: Yes, sir, so you
14 understand.

15 PRESIDING MEMBER LAURIE: -- I
16 understand the issue. And yet, power plants, as
17 we've noted, are generally -- well, but for down
18 south we haven't had any applications for power in
19 -- I don't know, when I think of RCRC membership,
20 does that include Kern and --

21 MR. JACKSON: It does not include Kern.
22 Inyo and Madera are our southernmost counties. We
23 come up to Fresno city limits.

24 PRESIDING MEMBER LAURIE: Okay.

25 MR. JACKSON: And go to the Oregon

1 border.

2 PRESIDING MEMBER LAURIE: I'd be
3 interested in having a further discussion with you
4 about the relationship between rural counties and
5 smaller power plants. I'd also be interested in
6 seeing when we're going to get an application for
7 a power plant really in the San Joaquin. It will
8 not happen in the foothills, I can't imagine.
9 Well, yeah, I guess I can imagine, but --

10 MR. JACKSON: Can't imagine it being
11 built.

12 PRESIDING MEMBER LAURIE: If you think
13 San Jose is bad folks, wait till you deal with
14 mountain people.

15 MR. JACKSON: There are actually
16 possibilities in the mountains, I believe. But we
17 would have to be extremely careful. There is
18 abundant water. There are industrially zoned
19 sites from what we used to call a timber industry.
20 And most of those facilities have power to them,
21 and they're abandoned. And they would be very
22 quick in all siting problems except water.

23 Now, if the state has a policy that
24 would allow -- I presume the State Water Board was
25 here this morning and explained their policy under

1 their order, where basically there's a series of
2 steps down to where you get to the kind of quality
3 water we have.

4 And we agree that as best possible we
5 ought to use the worst possible quality that will
6 fit the purpose. But, in our areas, in the
7 mountains, along some of the major transmission
8 lines, because of the fact that the hydro plants
9 are located there, as well, there are sites,
10 bombed-out industrial sites, that would be quite
11 appropriate. And there are people there who
12 believe that energy is a potential economy.

13 PRESIDING MEMBER LAURIE: What about
14 gas?

15 MR. JACKSON: There are gas pipelines
16 available in some places. We have not looked at
17 that and would be very much interested in working
18 with you or anyone else to take a look at logical
19 places to site next pipelines, near transmission
20 lines, on previously existing industrial land.
21 And we think that combination would be the
22 fastest.

23 PRESIDING MEMBER LAURIE: Excellent, and
24 thank you, sir, very much.

25 MR. O'HAGAN: Sorry, I sort of subsumed

1 the Tulare Basin into the San Joaquin Valley.

2 PRESIDING MEMBER LAURIE: No, that's
3 okay.

4 MR. JACKSON: All politicians do, so
5 it's okay.

6 (Laughter.)

7 MR. O'HAGAN: Thank you. One thing we
8 did have one project that was going to be filed in
9 Livingston, I think it was believed to have been a
10 Modesto Irrigation District project, but it was
11 never actually filed.

12 But, Mr. Gerald Meral is here now. And
13 so, introduce --

14 DR. MERAL: Thank you very much.

15 PRESIDING MEMBER LAURIE: Dr. Meral, how
16 are you this afternoon, sir.

17 DR. MERAL: Very good, thank you for the
18 invitation to appear before you.

19 You're honing in on an area that's very
20 important, increasingly important, I guess, with
21 all the siting that's going on. And the water
22 board, of course, has paid attention and you've
23 heard from them extensively on this.

24 But, our sense is that given a drought
25 situation, if a power plant has been allocated a

1 supply of fresh water that can be used for other
2 purposes, in a drought you've got a double whammy
3 in a sense. Most likely that power plant is going
4 to have to run more because there's less hydro
5 available, and also water's in less supply.

6 So you've elevated that power plant to
7 one of the highest and best uses by accident in a
8 sense. And that's all the more reason to try to
9 the utmost to prevent dedication of these fresh
10 water resources to new power plants.

11 And we've been a little bit involved in
12 some controversies over this because sometimes the
13 power plant operators rightly feel that if they're
14 forced to use reclaimed water, there are going to
15 be costs associated with that that they wouldn't
16 have if they just opened up the tap.

17 And while the Energy Commission
18 obviously has a lot to do, we would encourage you
19 to perhaps become involved in attempts to find
20 additional subsidies for the use of reclaimed
21 water such as proposition 13 provided. We have
22 extensive funds in proposition 13 to pay for the
23 use of reclaimed water for these kinds of
24 industrial facilities.

25 I'm pretty sure that Mr. Costa will

1 introduce another water bond. And this might be
2 an opportunity for you, at least through your
3 staff, to make an appearance to urge increased
4 funding in the area of recycled water. Because it
5 will become available for the sites that you're
6 going to have to site, the plants that you're
7 going to have to site.

8 And really is probably one of the most
9 realistic alternatives in many parts of the state
10 that, you know, do have this kind of water supply
11 available.

12 It's very hard for you to turn down a
13 power plant because it's using fresh water. If
14 it's the only alternative, you're probably going
15 to have to site it.

16 PRESIDING MEMBER LAURIE: Well, in
17 addition, one of the challenges that I think we
18 face in our hearing process is there's no Energy
19 Commission policy dealing with the mandatory use
20 of the dry cooling or alternative system.

21 We really only get to that question if
22 upon environmental review we find that water
23 service is significantly impacted.

24 As we had chatted about earlier today,
25 the Commission relies on readily available data

1 normally for those purposes. And more often than
2 not the data reflects the views of the local water
3 districts, that there's an adequate supply of
4 water to serve that project.

5 So if a local government agency says to
6 us, we'll serve, then the Energy Commission would
7 be challenged to say well, we have data in front
8 of us that says from a statewide perspective
9 there's a bigger question here.

10 And so that's a fundamental issue that
11 we face probably in every case.

12 DR. MERAL: Well, you're right on point
13 with a certain lawsuit that Mr. Jackson and I are
14 intimately familiar with.

15 (Laughter.)

16 DR. MERAL: Because, as you may know, we
17 brought a suit regarding the state water supply,
18 state water project supply, PCL v. DWR, and the
19 appellate court said that the state should stop
20 relying on what in a sense you're referring to,
21 which is paper water. Water that has been
22 contracted for, but which the state, at least, is
23 currently unable to deliver.

24 And we are hoping, as this suit is
25 perhaps settled or further litigated, that we can

1 get you better information about what's really
2 available. Because what they tend to do, just as
3 you're saying, is well, there's a contract for 2.-
4 whatever-it-is-million acrefeet at NWD, therefore
5 the water's going to be there. In fact, the
6 reliable delivery is half of that.

7 And so we are totally in sympathy with
8 that concern. You and many other planning
9 agencies have the same problem.

10 But we would urge you to at least look,
11 when you're in the state water project service
12 area, which is not everything you're dealing with,
13 at what the state system can reliably supply.
14 Because what you're getting back from the local
15 planning agency is their full contract, as opposed
16 to what DWR in bulletin 132, which is publicly
17 available, says actually can be delivered.

18 So that is one way you can probe a
19 little more deeply into what's really there.

20 PRESIDING MEMBER LAURIE: Okay, thank
21 you.

22 DR. MERAL: I think, you know, from our
23 point of view our sense is there's so many demands
24 for water, environmental demands, industrial,
25 agricultural, and so on, that to the extent power

1 plants can avoid making additional demands because
2 they are so rock solid and so uninterrupted, if
3 I may use that word, we urge you certainly to try
4 to either get the technology to the point where
5 they need little or no water, or get them onto the
6 reclaimed water source, which is really a good
7 source for most of these power plants.

8 They don't need superb quality the way
9 perhaps Silicon Valley does. They can use
10 recycled water, especially if it receives tertiary
11 treatment. And to the extent you can help us in
12 the Legislature get more funds for that, it'll
13 make your job easier, as well.

14 PRESIDING MEMBER LAURIE: Thank you.
15 Question for you. We talked a little this morning
16 about how available water resources are used in
17 the something like 45 percent of available
18 resources, available for environmental purposes.

19 We are at the point in the processing of
20 power plants where very serious interests are
21 clashing. Air quality versus power. Water supply
22 versus power. Community design versus power, et
23 cetera.

24 On the issue of environmental waters,
25 what percent of that set-aside is available for

1 flexible use? I'm not asking you to negotiate
2 here.

3 DR. MERAL: No, I understand.

4 PRESIDING MEMBER LAURIE: Because I
5 honestly don't have any understanding of where
6 that water goes.

7 DR. MERAL: One of the problems with
8 that figure, which would be a statewide figure
9 essentially, is that the vast majority of water
10 that's considered dedicated for environmental
11 purposes is actually in the wild and scenic rivers
12 of the north coast, the Eel, Trinity, Klamath and
13 so on, Smith.

14 And that water, even though it's been
15 dedicated in the wild and scenic rivers, would be
16 available for power plant cooling and so on by
17 appropriation. If someone showed up in Crescent
18 City and said they wanted to build a power plant,
19 there's nothing in the Wild and Scenic Rivers Act
20 to prevent that. I mean it would have to be done
21 in the right way and so on.

22 So the answer is probably the vast
23 majority of it, but it's not in the right place.
24 The water that's been dedicated in the central
25 valley for environmental purposes is a very small

1 fraction of that, and that's a lot less flexible
2 because the Sacramento River, which is the main
3 source of that water, is so under stress already
4 that -- and what's more, it, too, is largely in
5 the wrong place. I mean in terms of the
6 diversions out of the channel. That it's probably
7 not overly relevant to most of your discussion.
8 Because that water is not where you want to site
9 the power plants, by and large.

10 That's not entirely true, but by and
11 large that would be the case.

12 MR. JACKSON: The other thing to add to
13 that is that I live in Plumas County, which is the
14 watershed for the state water project. And it's
15 also PG&E's stairway of power in terms of
16 hydroelectric.

17 And so while you have numbers that
18 indicate that there's 3.2 million acrefeet of
19 water that falls in my county, and we only use
20 3000 acrefeet of it, in the rivers you are
21 presently using 98 percent of our river for your
22 hydropower. Because only 2 percent of the water
23 flows in the river.

24 DR. MERAL: That's true, because that
25 water is then available for use downstream after

1 it goes through the power plants.

2 PRESIDING MEMBER LAURIE: In a hydro
3 project what percentage of water is returned to
4 the waterway?

5 MR. JACKSON: Almost none.

6 DR. MERAL: Well, or all. I mean at the
7 end of the --

8 MR. JACKSON: Yeah, after -- when you
9 arrive at Lake Oroville --

10 (Laughter.)

11 MR. JACKSON: -- it all appears. But in
12 terms of the environment, in my county at least,
13 on the North Fork of the Feather River, except for
14 four holding ponds, the water is always in
15 tunnels.

16 PRESIDING MEMBER LAURIE: So it gets
17 diverted and is owned by downstream users?

18 DR. MERAL: Eventually, in most hydro
19 there is a later beneficial use of the water,
20 except for some environmental regulations the
21 water board or someone else has applied.

22 PRESIDING MEMBER LAURIE: Thank you.

23 DR. MERAL: Thank you.

24 PRESIDING MEMBER LAURIE: 'Afternoon,
25 Ms. Gaffney, how are you?

1 MS. GAFFNEY: Thank you. My name is
2 Kaitilin Gaffney and I'm here today speaking on
3 behalf of the Center for Marine Conservation.
4 We're a national environmental organization that's
5 dedicated to ocean protection. So I'll be
6 speaking from a slightly different perspective,
7 and maybe one that's good to have after all this
8 discussion about inland water and supply. I can
9 speak up for the coasts and the ocean water supply
10 issues, which may be good, since we may be
11 shifting the pressure towards the coast, since we
12 don't have the same supply issue there.

13 But ultimately what I'm going to ask you
14 is I think something that you've heard several
15 times, and the previous speaker also suggested, to
16 look towards alternatives that do not require
17 large volumes of fresh water, estuarine water, or
18 ocean water. So, basically the same plea.

19 And my suggestion, in response to the
20 question of how to expedite bringing new power
21 capacity on line in California, how to deal with
22 environmental constraints, is to try to solve the
23 environmental problems so that community doesn't
24 have to oppose a plant, as opposed to trying to
25 figure out ways to speed up the process without

1 taking those concerns into account.

2 We heard a lot of discussion this
3 morning, and in the earlier session this
4 afternoon, about dry cooling. And I really think
5 that that is where we need to be looking in the
6 future. We submitted comments on the EPA proposed
7 regs asking that dry cooling be considered in all
8 environments, not just in near-shore coastal
9 waters, but also offshore, because we think
10 there's strong evidence that power plants, even
11 those that draw from offshore coastal waters, have
12 very severe impacts on the environment.

13 PRESIDING MEMBER LAURIE: And what are
14 some of those? What would some of those impacts
15 be?

16 MS. GAFFNEY: I'm glad you asked.

17 (Laughter.)

18 MS. GAFFNEY: And I will be submitting
19 written comments with more detail and background.

20 The statistics are pretty staggering, 70
21 trillion gallons of water go through power plants
22 every year in this country. Certainly by volume
23 most of that is coastal waters, ocean water.

24 The concern that I have is not a supply
25 issue, but that water is not just -- it's not just

1 a mechanism for cooling power plants. It's an
2 ecosystem. It's habitat. And contained in that
3 water, both in fresh water systems and in the
4 ocean systems that I'm more familiar with, are
5 fish, are fish eggs, are fish larvae, are
6 invertebrate eggs, are invertebrate larvae.
7 There's all the life that is found in rivers and
8 the ocean.

9 And typically the consequence of going
10 through a power plant for those organisms is not
11 good, to put it mildly.

12 I'll give you some statistics from San
13 Onofre. In a normal year 110 tons of midwater
14 fish are entrained and 41 percent of those are
15 killed as they go through the San Onofre plant.

16 Cooling water intake has reduced kelp
17 beds off of San Onofre by 60 percent, resulting in
18 a 70 percent decline in the abundance of kelp-
19 associated fish species.

20 I have pages and pages of examples from
21 power plants from all over the country. Obviously
22 the impacts differ from plant to plant, different
23 areas of the state and the country have different
24 impacts.

25 But the take-home message is that even

1 though ocean waters are sort of the second
2 priority and considered, given some kind of
3 preference in terms of cooling water under state
4 policy, there are serious impacts associated with
5 using huge volumes of ocean water for power plant
6 cooling.

7 And to the extent that we can reduce
8 that volume or eliminate that volume, we would
9 have a very immediate and direct benefit on those
10 coastal ecosystems. And those are systems that
11 are facing increasing pressures from land-based
12 pollution, from over-fishing, from a variety of
13 different human sources.

14 So it's not as if this is the only thing
15 that they are trying to grapple with. We have --
16 CMC was recently involved in a petition to
17 actually list an ocean fish species under the
18 Endangered Species Act, the bocaccio rockfish.

19 We are looking at very serious pressures
20 in particularly our near-shore coastal
21 environments in California. So power plants are
22 one more thing that those systems have to try to
23 deal with. And the volumes are enormous.
24 Hundreds of millions of gallons a day being taken
25 out of frequently near-shore estuarine

1 environments that are particularly sensitive for
2 the species that use them.

3 PRESIDING MEMBER LAURIE: Given your
4 organization's experience, what is the ability of
5 a -- if you know, of a modern power plant to
6 mitigate its impacts on the ocean ecosystems?

7 MS. GAFFNEY: Well, we heard some
8 discussion this morning about how much better new
9 plants are compared to the older plants. And I
10 think it's true that we're looking at better
11 technologies, but a lot of those plants, you know,
12 plants that went in in the '50s or '60s, I would
13 hope that we're looking at better technologies.

14 The fact remains that the impacts are
15 very very high. You're still taking -- even if
16 the volume of water per unit of energy has dropped
17 because of increases in efficiency, when you're
18 looking at, you know, 800 million gallons of water
19 a day and everything in it, the impact is still
20 great.

21 And as we need more energy the net
22 continues to grow, even if we're becoming more
23 efficient.

24 I think we probably are improved from
25 where we were several decades ago, but it's still

1 a very serious problem.

2 DR. MERAL: Could I add just one thing
3 in addition to that. Just to quantify it, Friends
4 of the Earth and the Earth -- Institute brought a
5 lawsuit against Edison regarding the marine
6 impacts of San Onofre. And the mitigation
7 settlement was in the tens of millions of dollars.

8 And much of the mitigation money ended
9 up being spent in even San Diego County, they had
10 to go that far south to find places to do the
11 mitigation. It was quite difficult.

12 Another concern is that there is, of
13 course, a lot of problems with closures of beaches
14 in Huntington Beach in the last whole year,
15 actually, much of the beach was closed during that
16 time. There's now some indication that simply the
17 drawing in of cooling water by power plants in
18 that area has brought the discharge of pollutants
19 that was very far offshore, brought it much closer
20 to the beach, and perhaps contributed to the
21 enormous economic damage that was done when
22 Huntington Beach closed its beaches.

23 So, we're finding more and more problems
24 with these kind of marine intakes for cooling
25 water.

1 MS. GAFFNEY: I agree completely. I
2 think that's a very good point. That a) these are
3 very complex systems where it's difficult to
4 understand what the true impacts will be over
5 time, over 30, 40, 50 years, lifetime of a plant.
6 And so you see, in the case of Huntington Beach,
7 problems that no one would have predicted. And
8 some still don't -- they're still debating over
9 what's going on. But there are unexpected
10 consequences.

11 And so I guess the basic message that
12 I'm trying to get across is that you cannot remove
13 huge volumes of ecosystem without having a serious
14 impact on the environment. And if there's an
15 alternative to doing that, by using technologies
16 that use greatly reduced water sources, you know,
17 just closing the system so that the water's
18 recirculated can reduce the need for ocean water
19 by 95 percent. That's not even dry cooling.

20 So, don't ignore the application of
21 these technologies to the coastal environment and
22 the ocean-based power plants. Obviously there are
23 community concerns related to new power plants on
24 the coast that have nothing to do with marine
25 biology, visual impacts and the tremendous

1 affection Californians have for their coastline,
2 so that when new power plants are proposed in
3 coastal areas, the outcry is going to be
4 tremendous.

5 I think we need to look at ways that we
6 can produce energy closer to where it's being
7 used, to try to limit transmission losses. And
8 having huge plants on the coast that they have to
9 get their energy inland to where it's being used,
10 you know, may not be the answer for the future.
11 Although it was the way we did things in the past.

12 PRESIDING MEMBER LAURIE: Well, in fact,
13 one of the challenges is that the population on
14 the coast is at its maximum, and therefore the
15 people are moving inland, which requires more
16 power plants to be located inland where the demand
17 is, but not necessarily the resources, makes for
18 interesting energy planning.

19 MS. GAFFNEY: Right, no, I agree. I
20 would just argue we don't have the resources on
21 the coast, either.

22 Dry cooling has been used very
23 successfully. It's becoming more popular around
24 the world. There are 600 plants right now that
25 use dry cooling around the world. They've been

1 used in areas with climates that are very hot and
2 arid desert areas, in cold areas. I think it's a
3 very realistic technology, and one that we should
4 be looking at, because it is capable of reducing
5 so many of these problems.

6 PRESIDING MEMBER LAURIE: Thank you, Ms.
7 Gaffney, very much. Gentlemen.

8 At this time I would make the microphone
9 available for members of the public that wish to
10 comment or ask questions. And I thank the panel
11 tremendously, very well done.

12 Any member of the public wish to offer
13 comment?

14 Ms. Townsend-Smith, do you have any
15 questions or comments?

16 MS. TOWNSEND-SMITH: None, no.

17 PRESIDING MEMBER LAURIE: Okay, Mr.
18 Tomashefsky.

19 MR. TOMASHEFSKY: No.

20 PRESIDING MEMBER LAURIE: As we've
21 commented earlier, the purpose of this hearing is
22 to talk about the challenges of licensing power
23 plants in the future, and what barriers might
24 exist.

25 This issue is one of a series of issues

1 that we are examining and it's our intent to issue
2 a report roughly during the month of April. In
3 light of the fact that this is not a Legislative
4 mandate, if it's not issued until May, nobody will
5 care.

6 But these questions are important. And
7 obviously what we're finding is that again, for
8 the very -- maybe not for the very first time, but
9 more apparently now than ever before, different
10 interests are being pressured and are in direct
11 conflict. And there's going to have to be some
12 policy decisions determined.

13 Absent any questions or comments, I
14 would adjourn the meeting. And I thank you all
15 for your attendance.

16 (Whereupon, at 2:45 p.m., the workshop
17 was concluded.)

CERTIFICATE OF REPORTER

I, VALORIE PHILLIPS, an Electronic Reporter, do hereby certify that I am a disinterested person herein; that I recorded the foregoing California Energy Commission Workshop; that it was thereafter transcribed into typewriting.

I further certify that I am not of counsel or attorney for any of the parties to said workshop, nor in any way interested in outcome of said workshop.

IN WITNESS WHEREOF, I have hereunto set my hand this 14th day of February, 2001.

VALORIE PHILLIPS
